

Snow Survey and Water Supply Bulletin – January 1st, 2016

The January 1st snow survey is now complete. Data from 84 snow courses and 60 snow pillows around the province and climate data from Environment Canada have been used to form the basis for the following report¹.

Weather

Fall weather was variable across the province. A number of Pacific storm systems impacted coastal BC over the September through early December period, generally bringing warm temperatures and heavy precipitation. The 2015 active storm season was in strong contrast to the decreased storm frequency and relatively dry fall-winter periods that were experienced in 2013 and 2014.

Following storms in early December, the rest of the month was fairly stable, with modest precipitation. A high pressure ridge developed over BC towards the end of December, bringing dry weather into the New Year.

Overall, temperature trends through the October to December period were mixed across the province. October was generally warmer than normal across the province, except in the north-east. November was generally cooler than normal, with much cooler temperatures in the central interior. December transitioned back into warmer than normal throughout the province.

Precipitation patterns have also varied through the fall and into the winter. September was a wet month throughout most of the province. October and November were drier than normal through the north and south-west, with wetter than normal conditions in the south-east. December was wetter than normal in the south half of the province, and drier than normal in the north.

Snowpack

Snow basin indices range from a low of 53 % in the Stikine to a high of 143 % in the Similkameen (Table 1). In general, most of the province has near normal snow pack levels (90-110 %) for January 1st, 2016. A strong south to north gradient of snow pack levels exists, with normal or above normal snow pack in southern BC, lower than normal snow packs beginning in central BC, and extending to well below normal conditions in the north (Figure 1). Snow packs are below normal (70-80%) in the Upper Fraser West, Upper Fraser East, and Nechako basins, and well below normal (<70%) in the Peace, Skeena-Nass, Stikine, and Liard basins. Many individual survey locations in northern BC are observing very low snow water equivalent measurements. Above normal snow pack (>110%) is present in the Okanagan, Similkameen, and Boundary.

January's snow survey schedule features fewer individual snow survey measurements than occur in later survey periods in the year, therefore some January 1st snow basin indices are based on a very limited number of surveys (e.g. 1-2 surveys within the snow basin) (Table 1) making the data interpretation less robust than in survey periods later in the season.

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

Snow Survey and Water Supply Bulletin – January 1st, 2016

Table 1 - BC Snow Basin Indices – January 1, 2016

Basin	% of Normal	Basin	% of Normal
Upper Fraser West	77	Boundary	112
Upper Fraser East	77	Similkameen	143*
Nechako	79	South Coast	110
Middle Fraser	92	Vancouver Island	91
Lower Fraser	108	Central Coast	89
North Thompson	97	Skagit	109*
South Thompson	100	Peace	68
Upper Columbia	106	Skeena-Nass	65
West Kootenay	109	Stikine	53*
East Kootenay	105	Liard	54*
Okanagan	125	Northwest	NO DATA

*Note January 1st snow basin index values are based on limited observation points

Outlook

Fall and early-winter has seen the dissipation of warm water in the northern Pacific Ocean (i.e. the “Blob”) which has been present over the past two winter seasons, and was likely the key driver in the very warm winters and extremely low snow packs that occurred in southern BC in 2014-15. Strong El Niño conditions have developed over the equatorial Pacific regions over the past few months. The Climate Prediction Centre (CPC) at the U.S. National Weather Service/NOAA is forecasting a high likelihood of El Niño conditions persisting through until late-spring or early summer 2016.

In general, BC experiences warmer than normal winter and early-spring temperatures during strong El Niño events. Precipitation during historic El Niño events has been highly variable, with no strong trends across BC. Snow packs during El Niño events tend to be below normal across BC, however there has been significant historic variability and regional variation to this general trend. The last similarly strong El Niño event occurred over the winter of 1997-1998, and resulted in seasonal snow packs that were modestly below normal (e.g. provincial average of 94% of normal). Extreme low snow packs, such as those observed in southern BC in 2014-15, are not commonly associated with El Niño events. The effects of El Niño tend to be more pronounced during the mid- to late-winter and into spring.

Seasonal forecasts from Environment Canada are indicating a high likelihood of above-normal temperatures across British Columbia over the January to March period. Seasonal forecasts from NOAA are suggesting a more southern path for the Pacific jet stream through the January-March period, with increased precipitation for California, and decreased precipitation for British Columbia and the Pacific Northwest. Seasonal forecasts from Environment Canada do not indicate the likelihood of any strong seasonal precipitation

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

Snow Survey and Water Supply Bulletin – January 1st, 2016

anomalies, with the exception of a moderate likelihood of drier conditions in north-east BC. Seasonal precipitation forecasts tend to have much lower forecast skill than seasonal temperature forecasts, and therefore should be used with caution.

By early January, nearly half of the annual BC snowpack has typically accumulated. At this early stage in the season, there is limited indication that any regions of the province are developing increased seasonal flood risk. One exception is the high snow pack observed in the Similkameen basin, however this is based on limited survey observations for January 1st within the basin and therefore should be interpreted with caution. Currently observed low snow pack in some regions of the province, particularly the northern third of the province, is an early indication of the potential for lower than normal stream flow in the spring and summer this year. However, with three or more months left of snow accumulation, these outlooks could change significantly.

The River Forecast Centre will continue to monitor snow pack conditions and will provide an updated seasonal flood risk forecast in the February 1st 2016 bulletin, which is scheduled for release on February 9th.

Snow Survey and Water Supply Bulletin – February 1st, 2016

The February 1st snow survey is now complete. Data from 118 snow courses and 56 automated snow stations around the province and climate data from Environment Canada have been used to form the basis for the following report¹.

Weather

Weather through January was mixed, with dry periods, particularly in the beginning of the month, interspersed between more active storm cycles in the second half of the month. Overall, January temperatures were above normal across the province, with daily minimum temperatures being 3-5 °C above normal for many areas in south-east, central and northern BC. Temperatures in south-west BC were closer to normal, or slightly above normal.

January precipitation patterns have also varied across the province. South-west BC experienced near-normal to below-normal precipitation. Much of the rest of southern BC, including the southern Interior, Okanagan, Kootenay and Columbia, experienced above normal January precipitation. Central and northern BC experienced below to well-below normal precipitation.

Snowpack

Snow basin indices range from a low of 56% in the Stikine to a high of 122% in the Okanagan (Table 1). In general, most of the province has near normal or slightly below normal (80-110%) snow packs for February 1st, 2016, with a provincial average of 91% from all survey locations. A strong south to north gradient of snow pack levels exists, with normal or above normal snow pack in southern BC, lower than normal snow packs beginning in central BC, and extending to well below normal conditions in the north (Figure 1). Snow packs are below normal (70-80%) in the Upper Fraser West, Upper Fraser East, Nechako and Central Coast basins, and well below normal (<70%) in the Peace, Skeena-Nass, Stikine, and Liard basins. Above normal snow pack (>110%) is present in the Okanagan and Boundary.

Table 1: BC Snow Basin Indices – February 1, 2016

Basin	% of Normal	Basin	% of Normal

Snow Survey and Water Supply Bulletin – February 1st, 2016

Outlook

Fall and early-winter has seen the dissipation of warm water in the northern Pacific Ocean (i.e. the “Blob”) which has been present over the past two winter seasons, and was likely the key driver in the very warm winters and extremely low snow packs that occurred in southern BC in 2014-15. Strong El Niño conditions that developed over the equatorial Pacific regions over the past few months have likely peaked, and are now declining. The Climate Prediction Centre (CPC) at the U.S. National Weather Service/NOAA is forecasting a high likelihood of El Niño conditions persisting through until late-spring or early summer 2016.

In general, BC experiences warmer than normal winter and early-spring temperatures during strong El Niño events. Precipitation during historic El Niño events has been highly variable, with no strong trends across BC. Snow packs during El Niño events tend to be slightly below normal across BC, however there has been significant historic variability and regional variation to this general trend. The effects of El Niño tend to be more pronounced during the mid- to late-winter and into spring. Snow and weather conditions so far this season have been typical for an El Niño year, with the exception of northern BC, which is experiencing lower snow pack than is typical. In southern BC, snow packs are much better developed than the extremely low conditions that were experienced last year.

Seasonal forecasts from Environment Canada are indicating a high likelihood of above-normal temperatures across British Columbia over the February to April period, and an increased chance of warmer than normal temperatures through the extended forecast period into the summer months. Seasonal forecasts from NOAA are suggesting a more southern path for the Pacific jet stream through the February-April period, with increased precipitation for California, and decreased precipitation for British Columbia and the Pacific Northwest. Seasonal precipitation forecasts tend to have much lower forecast skill than seasonal temperature forecasts, and therefore should be used with caution.

Seasonal volume runoff forecasts (see below) are near normal for most basins across the province. Below normal seasonal runoff is forecast in the Kalamalka-Wood basin, and well above normal in the Nicola River and Similkameen River systems.

By early February, nearly two-thirds of the annual BC snowpack has typically accumulated. At this stage in the season, there are two emerging snow pack trends of note. First is the higher than normal snow packs that are being observed in the Okanagan which are trending towards the potential for elevated seasonal flood risk. Localized areas with high snow pack, such as locations in the Nicola River system, may also be following this trend. The second trend is in well below normal snow packs in northern BC (Peace, Skeena, Stikine, Liard and to a lesser extent Upper Fraser basins). With these low snow packs, combined with the increased likelihood of a warmer than normal spring melt season, there is an increased chance of below normal stream flow, particularly in the late-spring and into summer.

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

Snow Survey and Water Supply Bulletin – February 1st, 2016

For both spring flood risk and summer low flows, snow pack is just one of the important elements that determine whether or not extreme conditions will emerge. Weather, through the remaining portion of the snow accumulation season, the melt season, and into the summer, is also a key driver on whether or not flooding or low streamflows will occur.

The River Forecast Centre will continue to monitor snow pack conditions and will provide an updated seasonal flood risk and stream flow forecast in the March 1st 2016 bulletin, which is scheduled for release on March 8th.

Snow Survey and Water Supply Bulletin – March 1st, 2016

The March 1st snow survey is now complete. Data from 140 snow courses and 60 automated snow stations around the province and climate data from Environment Canada have been used to form the basis for the following report¹.

Weather

Temperatures across British Columbia continued to be well above normal through the month of February, with daily temperatures being 1-3 °C above normal through southern BC, and 3-5 °C above normal through the Kootenays, central, and northern BC. These warm temperatures have persisted throughout the 2015-16 winter (December, January, February), with temperature departures being 1-4 °C above normal across the province over the three month period.

February was generally a wet month, with a few heavier storm cycles mixed with drier and unsettled periods with lighter precipitation. Precipitation was above normal, with typical precipitation amounts in the range of 130-200% of normal across most of the province.

Snowpack

Wet weather through February led to increased snow packs across the province, and most regions of the province experienced an upswing of 5% to 10% in snow basin index values since last month. Snow basin indices range from a low of 55% in the Liard to a high of 123% in the Okanagan (Table 1). In general, most of the province has near normal or slightly below normal (80-110%) snow packs for March 1st, 2016, with a provincial average of 93% from all survey locations. A south to north gradient still exists across the province, however very low snow packs observed earlier in the season in northern BC have generally moderated. Below normal snow packs (65-80%) are present in the Upper Fraser East, Nechako, Central Coast, Skagit, Skeena-Nass, Stikine, and North-west, and well below normal (<65%) in the Liard. Above normal snow pack (>110%) is present in the Okanagan and Boundary.

Table 1: BC Snow Basin Indices – March 1, 2016

Basin	% of Normal	Basin	% of Normal
Upper Fraser West	85	Boundary	115

Snow Survey and Water Supply Bulletin – March 1st, 2016

In low and mid-elevations, warm temperatures through the winter led to an increase in the proportion of precipitation falling as rain rather than snow as well as mid-season snow melt. While melt does not typically occur until April, a few survey locations experienced a decrease in snow water equivalent values since the February survey. While the average for all snow survey locations across the province is 93% of normal, the average for locations below 1000 m elevation is just 67% of normal. Since the majority of the surveys taken across the province are higher elevation sites, diminished snow packs at low to mid-elevation may not be well reflected in the snow basin index values.

Streamflow

With warm temperatures, mid-season melt, and precipitation as rain, most rivers across British Columbia have experienced well above normal runoff (150% to 200% of median value) over the past one to two months. Snow melt runoff that typically flows later in the season has already passed through their watersheds. This advance in runoff timing may lead to an earlier freshet this season, both in terms of timing of peak flows and the recession to the low-flow season.

Outlook

Strong El Niño conditions that developed over the equatorial Pacific regions over the past few months peaked earlier in the winter and are expected to continue to decline into the spring. The Climate Prediction Centre (CPC) at the U.S. National Weather Service/NOAA is forecasting a high likelihood of El Niño conditions persisting through until late-spring or early summer 2016.

In general, BC experiences warmer than normal winter and early-spring temperatures during strong El Niño events. Precipitation during historic El Niño events has been highly variable, with no strong trends across BC. Snow packs during El Niño events tend to be slightly below normal across BC. However there has been significant historic variability and regional variation to this general trend. Snow and weather conditions so far this season have been typical for an El Niño year, with the exception of northern BC, which is experiencing lower snow pack than is typical. In southern BC, snow packs are much better developed than the extremely low conditions that were experienced last year.

Seasonal forecasts from Environment Canada are indicating a high likelihood of above-normal temperatures across British Columbia over the March to May period, and an increased chance of warmer than normal temperatures through the extended forecast period into the summer months.

Seasonal volume runoff forecasts (see table below) are near normal for most basins across the province. Above normal seasonal runoff is forecast for the Nicola River, Similkameen and Okanagan. Below normal seasonal runoff is forecast in the Cowichan River and Bulkley River systems.

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

Snow Survey and Water Supply Bulletin – March 1st, 2016

By early March, 80% of the annual BC snowpack has typically accumulated, with another one to two months remaining in the snow accumulation season. High snow pack in the Okanagan basin is an early indication of the potential for elevated seasonal flood risk in the region. Below normal snow pack, particularly in the Liard, and to a lesser extent the Upper Fraser, Nechako, Central Coast, Skeena-Nass, Stikine and Northwest, indicate an increased potential for low flows in the late-spring and summer.

The forecast of warmer weather through the spring, combined with warm temperatures already experienced this winter, is likely to be an important factor in this year's freshet season. With the advanced melt of some low to mid-elevation snow that has already occurred, continued warmer than normal temperatures would bring an earlier shift in the timing of the rise, peak and recession to summer flows of this year's freshet. While snow conditions were much different last year, late winter warm weather contributed to a 2 to 4 week advance in the timing of freshet flows in 2015.

For both spring flood risk and summer low flows, snow pack is just one of the important elements that determine whether or not extreme conditions will emerge. Weather, through the remaining portion of the snow accumulation season, the melt season, and into the summer, is also a key driver on whether or not flooding or low stream flows will occur.

The River Forecast Centre will continue to monitor snow pack conditions and will provide an updated seasonal flood risk and stream flow forecast in the April 1st 2016 bulletin, which is scheduled for release on April 7th.

Snow Survey and Water Supply Bulletin – April 1st, 2016

The April 1st snow survey is now complete. Data from 146 snow courses and 63 automated snow stations around the province and climate data from Environment Canada have been used to form the basis for the following report¹.

Weather

Temperatures across British Columbia continued to be well above normal through the month of March, with daily temperatures being 1-3 °C above normal through southern BC, and 2-4 °C above normal through the Kootenays, Central, and Northern BC. These warm temperatures have persisted throughout the 2015-16 winter.

March was generally a wet month, with a few heavier storm cycles mixed with drier and unsettled periods with lighter precipitation. A high pressure system with dry and very warm weather dominated the end of the month. Precipitation in March was above normal across most of the province, with typical precipitation amounts in the range of 130-200%. In the Central Interior, precipitation was closer to normal, and the Central Coast, North Coast and North-West were drier than normal.

Snowpack

Despite the warmer weather, wet conditions led to seasonal snow pack growth across most of the province through March. In Northern BC, many basins experienced a drop in basin index values since last month, and in the Okanagan and Boundary, basin index values increased. In general, snow basin indices are near normal (80-120%) across the province, with a provincial average of 91%. Below normal indices (65-80%) are present in the Upper Fraser West, Upper Fraser East, Nechako, and Skeena-Nass, and well below normal (<65%) in the Central Coast, Stikine, North-west, Liard and Skagit. Well above normal snow packs (>120%) are present in the Okanagan. Lower snowpack in the Upper Fraser is offset by slightly higher than normal snow packs in the Thompson River basin, and the overall Fraser River basin index is 96%.

Due to warm weather throughout the winter, low to mid elevation snow packs across the province are greatly diminished this season. While the provincial average for all April 1st surveys is 91% of normal, the average for sites below 1200 m elevation is 62% of normal, and just 44% of normal for sites below 1000m.

Warm weather towards the end of March and in early April has led to the onset of the melt season across the province. All of the provincial automated snow weather stations have recorded melt over the past week, as well as a number of manual surveys which experienced a loss of snow water equivalent between the March 1st and April 1st surveys. The transition from snow accumulation to snow melt is two to three weeks earlier than usual this season.

East Kootenay	99	Northwest	68

Streamflow

With warm temperatures, mid-season melt, and precipitation as rain, most rivers across British Columbia have experienced well above normal streamflow (150% to 200% of median value) over the past several months. Snow melt runoff that typically flows later in the season has already passed through their watersheds. As of early April, virtually all of the rivers in the province were flowing well above normal for the time of year. This advance in runoff timing is expected to continue to lead to an earlier freshet this season, both in terms of timing of peak flows and the recession to the low-flow season.

Outlook

Strong El Niño conditions that developed over the equatorial Pacific regions over the past few months peaked earlier in the winter and are declining. The Climate Prediction Centre (CPC) at the U.S. National Weather Service/NOAA is forecasting a high likelihood of El Niño conditions persisting through until late-spring or early summer 2016.

Seasonal forecasts from Environment Canada are indicating a high likelihood of above-normal temperatures across British Columbia over the April to June period, and an increased chance of warmer than normal temperatures through the extended forecast period into the summer months.

Seasonal volume runoff forecasts (see table below) are near normal for most basins across the province; above normal seasonal runoff (>120%) is forecast for the Nicola River, Similkameen and Okanagan and below normal seasonal runoff (<80%) is forecast for the Cowichan River.

High snow pack in the Okanagan basin indicates elevated seasonal flood risk in the region. Near-normal snow pack elsewhere in the province is an indication of normal seasonal flood

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

Snow Survey and Water Supply Bulletin – April 1st, 2016

risk. Below normal snow packs in the north and west indicate below normal seasonal risk, and watersheds in these areas would need to experience extreme weather conditions to develop flooding conditions this season. With a basin-wide index of 96% for the Fraser River, seasonal risk to lower Fraser River from Hope downstream is normal. The expected peak flow for the Fraser River at Hope is 8000-9000 m³/s; higher or lower flows are possible depending on weather conditions.

The forecast of warmer weather through the spring, combined with warm temperatures already experienced this winter, is likely to be an important factor in this year's freshet season. With the advanced melt of low to mid-elevation snow that has already occurred, continued warmer than normal temperatures are expected to continue to drive an advance in the freshet season. Typically peak flows in most snow-dominated rivers in the province reach their peak from mid-May through late-June. With the advance in melt already observed, and forecast for ongoing warm weather, the peak season is likely to be advanced to the late-April to early-June period for most rivers in the province.

Current weather forecasts for the next two weeks suggest on-going warm weather. Snow melt rates are expected to increase across the province, as snow packs ripen. River levels are expected to see significant rises over the next few weeks. In the short-term (through mid-April), flows are not expected to reach flood potential level. The River Forecast Centre is modelling streamflow across the province. Information regarding freshet conditions, including hydrologic model forecasts, is available on the [Freshet page](#) on the RFC website.

An advanced freshet is expected to put pressure on summer low flows in snow-melt dominated rivers across the province. With very low snow packs in the Central Coast, Skagit, Stikine and Liard, and low snow packs in the Upper Fraser, Nechako, Skeena and Northwest the risk for low flows this summer are elevated. Elsewhere in the province, limited seasonal snow pack at low to mid elevations will also add pressure to low flows later in the season, even in basins with normal snow basin indices.

For both spring flood risk and summer low flows, snow pack is just one of the important elements that determine whether or not extreme conditions will emerge. Weather, through the spring and summer, is also a key driver on whether or not flooding or low stream flows will occur. May and June are climatologically the wet season for the BC Interior. While indicators, like El Niño, have stronger linkages to seasonal temperature, precipitation is difficult to forecast beyond a one to two week horizon. Extreme wet or dry weather can significantly impact risks for peak flows and low flows.

The River Forecast Centre will continue to monitor snow pack conditions and will provide an updated seasonal flood risk and stream flow forecast in the May 1st 2016 bulletin, which is scheduled for release on May 9th.

Note that missing values reflect that forecasts were not made for that time interval

Disclaimer: Seasonal forecasts were developed using a Principle Component Analysis of snow pack, climate and streamflow data.

Cowichan Lake Inflows are based on a multi-variate regression analysis and reflects a normal scenario for summer weather conditions

The Standard Error in the Cowichan forecast reflects model error, and does not capture uncertainty over seasonal weather

There is inherent uncertainty in runoff forecasts including potential errors in data and the unpredictable nature of seasonal weather

Use at your own risk

Snow Survey and Water Supply Bulletin – May 1st, 2016

The May 1st snow survey is now complete. Data from 121 snow courses and 61 automated snow stations around the province, collected by the Ministry of Environment Snow Survey Program and partners, and climate data from Environment Canada have been used to form the basis of the following report¹.

Weather

Warm temperatures have persisted throughout the 2015-16 winter and spring. April weather was generally warm and dry, dominated by stable high pressure, and included an extended period of record heat in the third week of the month. Temperatures continued to be well above normal through the month of April with daily temperatures being 2-4 °C above normal across most of the province, except in the northwest, where temperatures were closer to normal. A few weather systems brought some precipitation, particularly to northern BC. Precipitation in southern BC was well below normal for April, with precipitation amounts typically in the 20-50% of normal range. In central and north-west BC, precipitation was closer to normal to above normal. In north-east BC, precipitation was 60-90% of normal.

Snowpack

The extremely warm periods in April led to significant and rapid melt of the provincial snow pack. May 1st snow basin indices ranged from 12% to 100% of normal, with a provincial average of 53%. The provincial average saw a decline of 38% from the April 1st value of 91%. The 2016 May 1st provincial average basin index is a new record low (measured since 1980), and is 13% below the previous low of 66%, observed in 1980. Of the 183 snow survey measurements made for the May 1st period, 33 stations, or 18%, observed new record lows, with many locations having 40 to 50 years of record. Low and mid-elevation snow is largely gone for all areas of the province with snow remaining only at high elevation.

Variability in snow pack conditions exists across the province. Snow packs are well below normal (<50%) through most the north half of the province and extending into the Cariboo and Central Coast, and in the Skagit, Similkameen and East Kootenay. In the Okanagan, Boundary, West Kootenay, Peace, Nechako, Vancouver Island, Lower Fraser and Upper Columbia, snow packs are low (60-75%). Snow pack is normal in the North Thompson and South Thompson.

May 1st snow conditions are more typical of those observed in a normal June 1st period, indicating that snow melt this season is three to four weeks ahead of normal.

East Kootenay	42	Northwest	12

Streamflow

With warm temperatures and rapid snow melt, most rivers across British Columbia experienced well above normal streamflow through April. Snow melt runoff that typically flows later in the season has already passed through their watersheds. As of early May, snow melt driven rivers in the province continue to flow well above normal for the time of year. In rivers with limited snow melt contribution to streamflow, such as Vancouver Island, the early melt and dry spring has led to below normal streamflow as of early-May. Also, in north-east BC, some rivers are seeing flows decline to below normal for this time of year, as the influence from this season's snow melt runoff is waning.

The advance in runoff timing is expected to continue to lead to earlier timing of peak flows and recession to the low-flow season across the province. The shift in timing echoes the pattern in snow melt, with many rivers experiencing flow conditions that are 3-4 weeks or more ahead of normal.

Outlook

Strong El Niño conditions that developed over the equatorial Pacific regions over the past few months peaked in the winter and are declining. The Climate Prediction Centre (CPC) at the U.S. National Weather Service/NOAA is forecasting El Niño (ENSO) conditions to transition into neutral conditions by late-spring/early summer 2016, and an increasing likelihood of moving towards La Niña conditions into the fall/winter of 2016. In the northern Pacific Ocean, below normal sea surface temperature anomalies have replaced the "blob" of warm water that persisted last year. However, near-shore water along the BC, Washington and Oregon coasts remains warmer than average, with warm-phase Pacific Decadal Oscillation (PDO) patterns being observed.

Snow Survey and Water Supply Bulletin – May 1st, 2016

Seasonal forecasts from Environment Canada are indicating an increased likelihood of above-normal temperatures across British Columbia over the May to July period, and into the extended forecast period of the late summer months. The warmer than average seasonal forecast is consistent with historic weather typically observed during positive in-phase ENSO and PDO conditions.

Seasonal volume runoff forecasts (see table below) are below normal for most basins across the province. The exceptions are above normal seasonal runoff (>115%) forecast for the Nicola River and Okanagan. Seasonal runoff models are influenced by antecedent runoff volumes and calibrated based on historic observed conditions, including the seasonal distribution of flows. In years like this, where spring runoff is much earlier than has typically been observed in the historic record, there is increased uncertainty over the accuracy and performance of the forecast models.

With significant snow melt already occurring, many river basins are approaching, or have passed, the peak of the freshet season. In mid-sized watersheds with limited high elevation terrain in the south and central interior, the peak of the freshet season may already have occurred. This includes the Similkameen River, tributaries in the Okanagan basin, Salmon River, Nicola River upstream of Nicola Lake, and similar surrounding rivers. In the larger river systems of the province, and rivers that drain higher elevation alpine terrain, the peak flow season is expected to continue to be 3-4 weeks earlier than normal, but have not yet occurred. For the North Thompson River the peak season may extend until mid-May, mid-to-late May for the Fraser River, Skeena River and tributaries, and early to mid-June for the South Thompson River and tributaries, again all 3-4 weeks earlier than normal. With a May 1st snow basin index of 69% of normal, the Fraser River at Hope has a revised forecasted peak flow of 6500-7000 m³/s.

The advanced freshet is expected to put pressure on summer low flows in snow-melt dominated rivers across the province. With the current very low snow packs remaining in the Upper Fraser, Middle Fraser, Nechako, Similkameen, East Kootenay, Central Coast, Stikine, Skeena, Liard, and Northwest, the risk for low flows this summer are elevated. Elsewhere in the province, the early shift in the snow melt season will also add pressure to low flows later in the season, even in basins with normal snow basin indices (e.g. North and South Thompson). In the northeast and in lower elevation coastal watersheds, summer rainfall is particularly important for sustaining summer flows, and will be a big determinant of the flows that will be experienced through this summer.

For both spring flood risk and summer low flows, snow pack is just one of the important elements that determine whether or not extreme conditions will emerge. Weather through the spring and summer is also a key driver in determining if flooding or low stream flows will occur. May and June are climatologically the wet season for the BC Interior. However precipitation is difficult to forecast beyond about a week and longer term trend forecasting is not reliable. Extreme wet or dry weather can significantly impact the likelihood of peak

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

Snow Survey and Water Supply Bulletin – May 1st, 2016

and low flows, so although snow packs around the province are low, late spring and summer precipitation will play an important role in determining streamflows.

Current weather forecasts for the next two weeks suggest cooler temperatures with rainfall in some locations through the short-term, and warm weather emerging through the middle of the month. River levels are expected to remain fairly stable through this period. The River Forecast Centre is modelling streamflow across the province. Information regarding freshet conditions, including hydrologic model forecasts, is available on the [Freshet page](#) on the RFC website.

The River Forecast Centre will continue to monitor snow pack conditions and will provide an updated seasonal flood risk and stream flow forecast in the May 15th 2016 bulletin, which is scheduled for release on May 24th.

1 kdam³=1,000,000 m³

Note that missing values reflect that forecasts were not made for that time interval

Disclaimer: Seasonal forecasts were developed using a Principle Component Analysis of snow pack, climate and streamflow data.

Cowichan Lake Inflows are based on a multi-variate regression analysis and reflects a normal scenario for summer weather conditions

The Standard Error in the Cowichan forecast reflects model error, and does not capture uncertainty over seasonal weather

There is inherent uncertainty in runoff forecasts including potential errors in data and the unpredictable nature of seasonal weather

Use at your own risk

Snow Survey and Water Supply Bulletin – May 15th, 2016

The May 15th snow survey is now complete. Data from 26 snow courses and 62 automated snow stations around the province, collected by the Ministry of Environment Snow Survey Program and partners, and climate data from Environment Canada have been used to form the basis of the following report¹.

Weather

Weather through the first half of May has been generally warm and dry across British Columbia, with periods of atmospheric instability and showers. Temperatures have continued to be warmer than normal, with extremely warm weather early in the month. Precipitation across the province has been below normal, with some areas in northern BC experiencing wetter than normal conditions.

Snowpack

The provincial snow pack has continued to melt at a rapid rate. Most snow survey locations experienced 100-300mm of snow water equivalent loss over the May 1st to May 15th period, with current melt rates of 10-20mm per day being observed at most Automated Snow Weather Stations.

May 15th snow basin indices have declined since the May 1st indices, with the provincial average dropping from 53% to 39% over the period. The 2016 May 15th provincial average basin index is a new record low (measured since 1980). May 15th indices are extremely low (<60%) across the province, except in the North Thompson, South Thompson, and Upper Columbia, where indices are in the 70-86% of normal range for this time of year.

The low May 15th snow basin indices reflect the accelerated melt of the snow pack this season due to the extremely warm spring, rather than a lack of seasonal accumulation. May 15th snow packs this year are more typical of mid-June conditions, indicating that snow melt this season continues to progress about four weeks ahead of normal.

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

West Kootenay	44	Stikine	1
East Kootenay	12	Liard	NO DATA
Okanagan	35	Northwest	NO DATA

1. ‘No Data’ indicates that no snow surveys were conducted within the basin during this survey period

Streamflow

Freshet runoff echoes the pattern in snow melt, with many rivers experiencing flow conditions that are 3-4 weeks or more ahead of normal conditions. Since May 1st many rivers have experienced a transition from well-above normal flows, to near-normal or below-normal flows as of mid-May.

Outlook

Strong El Niño-Southern Oscillation (ENSO) conditions that developed over the equatorial Pacific regions over the past winter are now rapidly declining, and are expected to reach neutral conditions over the next couple of months. The Climate Prediction Centre at the U.S. National Weather Service/NOAA has issued a “La Niña Watch” as modelling is indicating a high likelihood of La Niña conditions developing through the summer and fall of 2016. In the northern Pacific Ocean, temperature anomalies continue to decline offshore, and increase near-shore to British Columbia, indicating a potential warm-phase Pacific Decadal Oscillation (PDO) pattern.

Seasonal forecasts from Environment Canada are indicating an increased likelihood of above-normal temperatures across British Columbia over the May to July period, and into the extended forecast period of the late summer months. The warmer than average seasonal forecast is consistent with historic weather typically observed during positive in-phase ENSO and PDO conditions.

Most rivers have likely experienced their peak flow level for this season, and freshet flows are now receding. In rivers with a large proportion of high-elevation terrain, including the South Thompson River and upper Columbia River, the peak of the freshet is expected over the next few weeks. Seasonal flood risk due to snow melt is now limited across the province, however flooding could still occur from significant rainfall events.

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

Snow Survey and Water Supply Bulletin – May 15th, 2016

The advanced freshet is expected to put pressure on summer low flows in snow-melt dominated rivers across the province. In many of the smaller and low- to mid-elevation watersheds of the province (e.g. in Central Interior and South Interior), the transition to seasonally lower than normal flows has begun, and the trend is expected to expand to larger watersheds over the next few weeks. The influence of the snowmelt season occurring about a month early this year is expected to continue through the summer. While the volume of runoff is expected to be near normal throughout this year's freshet in most areas, the majority of this volume will occur through April and May, rather than May and June, as normally occurs. While the impact of this will vary from river to river across the province, the proportion of flows in June, July and August that are derived from snow melt will be greatly reduced. In the northeast and in lower elevation coastal watersheds, snow melt usually plays a minor role in summer flows, and rainfall is particularly important for determining the flows that are experienced through the summer.

For both spring flood risk and summer low flows, snow pack is just one of the important elements that determine whether or not extreme conditions will emerge. Extreme wet or dry weather can significantly impact the likelihood of peak and low flows. If the remainder of the spring and summer has near normal precipitation, below normal flows are likely throughout the province over the summer.

Current forecasts for the week suggest cool and unsettled weather. Significant rainfall is not expected to either pose localized flood risk, or ease the trend towards earlier low flows. The River Forecast Centre is modelling streamflow across the province. Information regarding freshet conditions, including hydrologic model forecasts, is available on the [Freshet page](#) on the RFC website. Seasonal information on drought and drought levels is available on the [BC Drought Information Portal](#).

The River Forecast Centre will continue to monitor snow pack conditions and will provide an updated seasonal flood risk and stream flow forecast in the June 1st 2016 bulletin, which is scheduled for release on June 8th.

Snow Survey and Water Supply Bulletin – June 1st, 2016

The June 1st snow survey is now complete. Data from 29 snow courses and 62 automated snow weather stations around the province, collected by the Ministry of Environment Snow Survey Program and partners, and climate data from Environment Canada have been used to form the basis of the following report¹.

Weather

Weather through the first half of May was generally warm and dry across British Columbia, with periods of atmospheric instability and showers. The second half of the month transitioned into cooler and wetter weather. May temperatures were generally 1-2 °C above normal across the province. Precipitation patterns were varied, with below normal precipitation in the south-west and west central BC, above normal precipitation in the north-east, and near normal precipitation elsewhere in the province.

Snowpack

The provincial snow pack has continued to melt at a rapid rate. Most snow survey locations experienced 150-300 mm of snow water equivalent loss over the May 15th to June 1st period. With the heat spell over the past several days, snow melt rates observed at automated snow weather stations have been in the 35 to 75 mm/day range.

Snow basin indices continue to decline relative to normal values, reflecting the extremely early melt this season. June 1st snow basin indices range from 2% to 69% (Table 1). Snow basin indices are extremely low (<50%) for most regions in the province, except in the North Thompson, South Thompson and Upper Columbia which are at 60-70% of normal.

Table 1: BC Snow Basin Indices – June 1, 2016

Basin	% of Normal	Basin	% of Normal
Upper Fraser West	0	Boundary	16
Upper Fraser East	5	Similkameen	8
Nechako	12	South Coast	32
Middle Fraser	12	Vancouver Island	28
Lower Fraser	21	Central Coast	0
North Thompson	69	Skagit	No Data
South Thompson	68	Peace	26
Upper Columbia	63	Skeena-Nass	2
West Kootenay	35	Stikine	2
East Kootenay	8	Liard	No Data
Okanagan	26	Northwest	No Data

1. 'No Data' indicates that no snow surveys were conducted within the basin during this survey period

The provincial average index for June 1st is 23%, and is a record low for this time of year (based on records to 1980). Nearly half of all observations from June 1st recorded little or no snow (<10 mm snow water equivalent). The low June 1st snow basin indices reflect the

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

Snow Survey and Water Supply Bulletin – June 1st, 2016

accelerated melt of the snow pack this season due to the extremely warm spring, rather than a lack of seasonal accumulation. Current snow conditions are more typical of late-June or early-July.

Streamflow

Freshet runoff echoes the pattern in snow melt, with many rivers experiencing flow conditions that are 3-4 weeks or more ahead of normal conditions. While April runoff was generally well above normal across the province, flows eased to near normal for May as rivers transitioned to the declining limb of the snow melt runoff cycle. Rivers across the Interior of BC are expected to see lower than normal runoff through the rest of the season, particularly in June-July when runoff is usually still strongly influenced by snowmelt.

Most rivers have likely experienced their peak levels for the year, unless an extreme rainfall event occurs in June or early-July. Preliminary data from the Fraser River at Hope (Water Survey of Canada gauge 08MF005) suggests the river reached a peak flow of 6130 m³/s on May 8th. This is the earliest date in the season that the river has reached its maximum level, and is the second lowest peak flow on record (from 1912 to present). Typically the Fraser River at Hope peaks in the middle of June.

Outlook

The El Niño-Southern Oscillation (ENSO) conditions that have been prevalent over the past winter are diminishing, with declining temperature anomalies in the equatorial Pacific Ocean. Modelling from the Climate Prediction Centre at the U.S. National Weather Service/NOAA is indicating that neutral ENSO conditions are expected over the May to July period, and a “La Niña Watch” has been issued as La Niña conditions are favoured to develop through the summer and fall of 2016.

Seasonal forecasts from Environment Canada are indicating an increased likelihood of above-normal temperatures across British Columbia over the June to August period. Most rivers in the province have likely experienced their peak flow for this season, and freshet flows are now receding. Seasonal flood risk due to snow melt is now limited across the province, however flooding could still occur from significant rainfall events.

The advanced freshet is expected to put pressure on summer low flows in snow-melt dominated rivers across the province. In many of the smaller and low- to mid-elevation watersheds of the province (e.g. in Central Interior and South Interior), the transition to seasonally lower than normal flows has begun, and the trend is expected to expand to larger watersheds over the next few weeks. The influence of the snowmelt season occurring about a month early this year is expected to continue through the summer. While the total volume of runoff is expected to be near normal throughout this year’s freshet in most areas, the majority of this volume has occurred through April and May, rather than May and June, as normally occurs. While the impact of this will vary from river to river across the province, the proportion of flows in June, July and August that are derived from snow melt will be

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

Snow Survey and Water Supply Bulletin – June 1st, 2016

greatly reduced. In the northeast and in lower elevation coastal watersheds, snow melt usually plays a minor role in summer flows, and rainfall is particularly important for determining the flows that are experienced through the summer.

For both spring flood risk and summer low flows, snow pack is just one of the important elements that determine whether or not extreme conditions will emerge. Extreme wet or dry weather can significantly impact the likelihood of peak and low flows. If the remainder of the spring and summer has near normal precipitation, below normal flows are likely throughout the province over the summer.

Current forecasts for the week suggest a transition out of the hot spell experienced last weekend as a cold low moves across the province. This is expected to bring cooler temperatures and moderate rainfall.

The River Forecast Centre is modelling streamflows across the province. Information regarding freshet conditions, including hydrologic model forecasts, is available on the [Freshet page](#) on the RFC website. Seasonal information on drought and drought levels is available on the [BC Drought Information Portal](#).

The River Forecast Centre will continue to monitor snow pack conditions and will provide an updated seasonal flood risk and stream flow forecast in the June 15th 2016 bulletin, which is the final snow bulletin for the season, scheduled for release on June 23rd.

Snow Survey and Water Supply Bulletin – June 15th, 2016

The June 15th snow survey is now complete. Data from 5 snow courses and 62 automated snow weather stations around the province, collected by the Ministry of Environment Snow Survey Program and partners, and climate data from Environment Canada have been used to form the basis of the following report¹.

Weather

Weather through the first half of June has generally been seasonable, with periods of unsettled weather and showers across the province. A high pressure system in early-June brought hot temperatures through southern BC. Since early-June a number of cold low systems have swept across the province, bringing cooler temperatures and wetter weather. Precipitation through the first part of June has been variable across the province, with below normal rainfall in western and southwestern BC, and above normal precipitation in central BC and the north-east.

Snowpack

Snow packs are generally depleted at snow monitoring locations across the province as of June 15th, with only 12 of the 62 automated snow weather stations recording more than 50 mm of snow water equivalent. Where snow packs were sufficient to support melt, observed melt over the June 1st to June 15th period was typically in the 200 to 400 mm range.

Snow basin indices are extremely low for the June 15th period. Since very few manual snow surveys are collected on June 15th (historically and for the 2016 survey period), snow conditions are largely interpreted from automated snow weather station data. As a result, many basins have limited data to assess snow basin index values.

Table 1: BC Snow Basin Indices – June 15, 2016

Basin	% of Normal	Basin	% of Normal
Upper Fraser West	NO DATA	Boundary	5
Upper Fraser East	5	Similkameen	1
Nechako	NO DATA	South Coast	26
Middle Fraser	17	Vancouver Island	6
Lower Fraser	18	Central Coast	0
North Thompson	33	Skagit	NO DATA
South Thompson	43	Peace	7
Upper Columbia	29	Skeena-Nass	NO DATA
West Kootenay	20	Stikine	0
East Kootenay	1	Liard	NO DATA
Okanagan	0	Northwest	NO DATA

1. 'No Data' indicates that no basin index snow surveys were conducted within the basin during this survey period.

Snow Survey and Water Supply Bulletin – June 15th, 2016

Low snow basin indices for June 15th reflect the early season melt that happened this spring. Based on historic automated snow weather station data, conditions this year on June 15th are more typical of early-July conditions, indicating that this season's melt continues to be 3-4 weeks ahead of normal.

Streamflow

Freshet runoff echoes the pattern in snow melt, with many rivers experiencing flow conditions that are 3-4 weeks or more ahead of normal conditions. While April runoff was generally well above normal across the province, flows eased as rivers have transitioned to the declining limb of the snow melt runoff cycle. Rivers across the Interior of BC are generally at 25% to 75% of normal flow levels for this time of year. These represent flows generally in the 5th to 15th percentile range. The exception to this is in the central Interior and in north-east BC, where flows are closer to normal, or even above normal, as the result of wet weather over the past few weeks. On Vancouver Island and smaller, non-glaciated drainage basins in south-west BC, river levels are extremely low for this time of year as the result of drier weather and early snow melt, with current flows typically in the 1st to 5th percentile range.

Outlook

The Climate Prediction Centre at the U.S. National Weather Service/NOAA has ended their El Niño Advisory as sea surface temperature anomalies in the equatorial Pacific Ocean have declined to neutral levels. A “La Niña Watch” has been issued as modelling is indicating that La Niña conditions are favoured to develop by the fall-winter of this year. Seasonal forecasts from Environment Canada indicate an increased likelihood of above-normal temperatures across British Columbia over the June to August period.

Most rivers have experienced their peak levels for the year, unless an extreme rainfall event occurs in late-June or early-July.

The advanced freshet is expected to put pressure on summer low flows in snow melt-dominated rivers across the province. Through most of the province, the transition to seasonally lower than normal flows occurred. The influence of the snow melt season occurring about a month early this year is expected to continue through the summer, with the largest departures from normal flows occurring in late-June and through July. By August and into September, rainfall is an important factor in determining streamflow as the influence from snow melt diminishes. While the impact of this will vary from river to river across the province, the proportion of flows in June, July and August that are derived from snow melt will be greatly reduced. In the northeast and in lower elevation coastal watersheds, snow melt usually plays a minor role in summer flows, and rainfall is particularly important for determining the flows that are experienced through the summer.

This is the final Snow Survey and Water Supply Bulletin for the 2016 season. The River Forecast Centre will continue to monitor streamflow and weather across the province, and

1. Every effort is made to ensure that data reported on these pages are accurate. However, in order to update the graphs and indices as quickly as possible, some data may have been estimated. Please note that data provided on these pages are preliminary and subject to revision upon review.

Snow Survey and Water Supply Bulletin – June 15th, 2016

issue Water Supply and Streamflow Bulletins throughout the summer as conditions warrant. Seasonal information on drought and drought levels is available on the [BC Drought Information Portal](#).
