

Invermere Timber Supply Area Vegetation Resources Inventory

Statistical Adjustment

Version 2.0

**PREPARED BY:
HUGH CARTER, MSC, RFT
TIMBERLINE NATURAL RESOURCES GROUP LTD.**

September 2009

EXECUTIVE SUMMARY

The Invermere Timber Supply Area (TSA) stakeholders initiated a Vegetation Resources Inventory (VRI) program in 2007 to upgrade and adjust their existing inventory. The stakeholders determined that the existing photo interpreted Forest Inventory Planning (FIP) inventory (1995 photos) was acceptable. The FIP data was rolled over to VRI format in 2000 and this dataset was used for the VRI Phase II design and statistical adjustment.

The target population was Crown land in the Invermere TSA, outside parks, vegetated treed (VT) and at least 30 years in 2007 (457,587 ha). The primary objectives of this program were to:

1. Develop statistically unbiased volume estimates for stands > 30 years in the VT landbase;
2. Achieve an overall $\pm 10\%$ sampling error (95% probability) for live volume;
3. Collect coarse woody debris estimates at all Phase II plots; and,
4. Complete additional destructive sampling of lodgepole pine (PI) to test (as part of a separate project) the ability of the Provincial PI taper equations to predict the taper of smallwood PI in the Invermere TSA.

McColl Forestry (McColl) established 119 Phase II plots (2007 and 2008 field seasons) and destructively sampled 120 trees (2008 field season) as part of the Net Volume Adjustment Factor program. Height, age, basal area, stems per hectare, and live net merchantable volume were adjusted following Ministry of Forests and Range (MFR) VRI statistical adjustment methods. All projections and volumes were generated using VDYP7. Following adjustment, the results are:

- The average live net merchantable volume (12.5cm +) is 185m³/ha, a 12% increase over the original inventory estimates.
- The average polygon height is 19.7m, a 5% decrease versus the original inventory estimates.
- The average polygon age is 137 years, a 6% decrease versus the original inventory estimates.
- The average site index is 12m, a 3% decrease versus the original inventory estimates.
- The average basal area is 28m²/ha, an 8% increase versus the original inventory estimates.
- The average density is 939 stems per hectare, a 12% increase versus the original inventory estimates.

The overall volume statistics were $\pm 13\%$ (95% probability) which did not achieve the target of $\pm 10\%$ (95% probability). This is likely due to the use of basal area and stems per hectare in the yield model as these attributes exhibited relatively large variability in the TSA.

The key recommendations from this project are that:

1. The adjusted height, age, basal area, stems per hectare and volume be used in the timber supply analysis base case in Timber Supply Review;
2. The stakeholders use the PI NVAF data together with other destructively sampled PI tree data to assess possible taper issues in the small PI population of interest.
3. The stakeholders consider the CWD and forest health data provided in this report as a starting point for investigating specific CWD and forest health issues.

1.0 INTRODUCTION

1.1 Vegetation Resources Inventory Overview

The Vegetation Resources Inventory (VRI) is the Ministry of Forests and Range's (MFR) forest inventory standard on public lands in BC. Where possible, forest licensees must use the VRI standard in their Data Package submission for Timber Supply Review (TSR).

The VRI is a four-step process (Figure 1):

1. Phase I (unadjusted inventory data) – Estimates of polygon attributes are derived for the target population, usually from photo-interpretation.
2. Phase II (ground sample data) – Measurements are taken from randomly located ground samples in the target population.
3. Net Volume Adjustment Factor (NVAF) sampling – Random trees are selected for stem-analysis from the Phase II samples to develop adjustment ratios that correct taper and decay estimation bias.
4. Statistical Adjustment Phase – The Phase I estimates are adjusted using the NVAF-corrected Phase II ground samples to provide an adjusted unbiased estimate of forest inventory attributes. The final product is an adjusted VRI database.

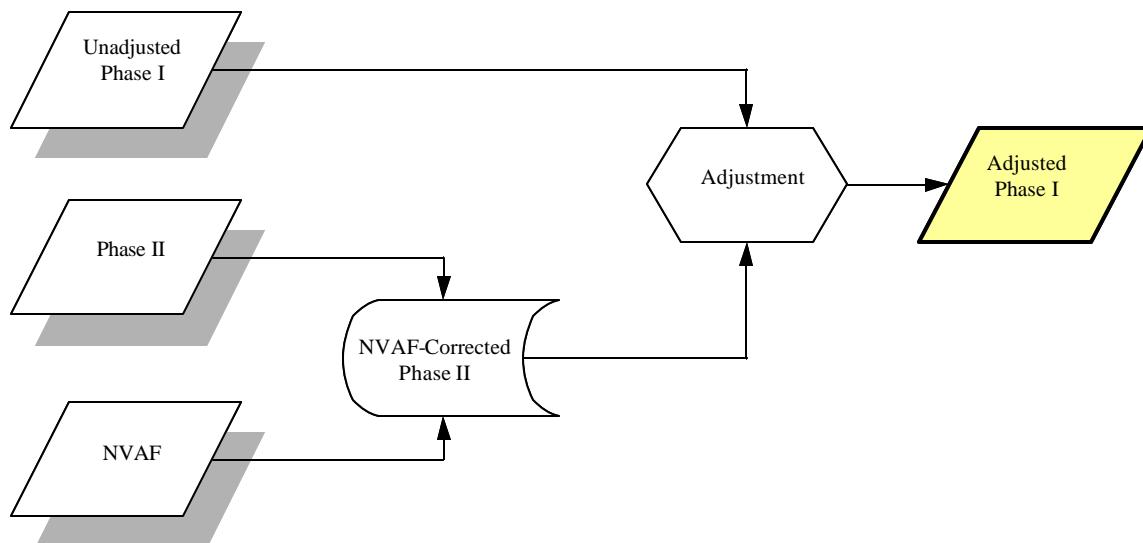

Figure 1. VRI Flow-chart.

1.2 Invermere TSA VRI Program

The Invermere Timber Supply Area (TSA) stakeholders initiated a VRI program in 2007. The first step was to develop the VRI strategic implementation plan (VSIP)¹ which recognized that the existing photo interpreted inventory suitably addressed the stakeholder's information needs but that a Phase II program was required to adjust and correct for bias in height, age, and volume. There was also a need to quantify (at a broad level) the amount of coarse woody debris in the TSA, identify forest health issues, and report on dead wood volumes in the TSA.

The inventory used in this project was developed in 1995 using the standards at the time. This Forest Inventory Planning (FIP) data was rolled over to the VRI format in 2000. Depletion updates were provided by Tembec in September 2007 which included Tembec's harvested updates to September 2007.

Timberline Natural Resource Group Ltd. (Timberline) completed the Phase II VRI project implementation plan (VPIP)² in 2007 using the most current data at the time. McColl Forestry Ltd. completed the Phase II ground sampling during the 2007 and 2008 field seasons and the NVAF program during the 2008 field season. Timberline completed the NVAF analysis and statistical adjustment of the Phase I.

1.3 Problem Statement

The Invermere TSA inventory is based on photo-interpreted inventory attribute estimates using the FIP procedures which were rolled over to VRI. The Provincial Chief Forester requires that the bias implicit in photo-interpretation be removed and the statistical precision of the inventory be known before the Annual Allowable Cut (AAC) is determined. The VRI is designed to provide the Chief Forester with a level of comfort in the inventory for TSR. The Chief Forester requested information quantifying dead wood and forest health agents in the TSA.

The objectives of the Phase II program (from the VPIP) were to:

1. *Develop statistically unbiased volume estimates for stands at least 30 years old in the Invermere TSA vegetated treed (VT) land base;*
2. *Achieve an overall ±10% sampling error (95% probability) for live volume in the Invermere TSA;*
3. *Collect coarse woody debris information in all Phase II plots to support landscape level biodiversity objectives; and*
4. *Collect site series information to get improved information on landscape level biodiversity.³*

² Timberline Natural Resource Group Ltd., July 2008. *Invermere Timber Supply Area Vegetation Resources Inventory Resources Phase II Project Implementation Plan Version 3.2*. Unpublished. Pp. 32.

³ This data was collected for use by the Invermere stakeholders.

1.4 Analysis and Reporting Objectives

The analysis objectives were to:

1. *Compile the 2007/2008 VRI Phase II (ground data) to MFR standards;*
2. *Adjust the VRI Phase II net merchantable volume using NVAF data;*
3. *Complete the statistical adjustment of the inventory; and*
4. *Summarize the plot data to report on dead down wood and forest health issues from the ground sampling program.*

The report objective is to:

1. *Document the statistical adjustment procedures used in this analysis;*
2. *Report on the results;*
3. *Identify areas of uncertainty in the data ; and*
4. *Summarize the dead wood and forest health results, and provide recommendations for its use in TSR*

1.5 Terms of Reference

Timberline prepared this report for Marcie Belcher, *RFT* (Tembec) and the Inventory TSA stakeholders. Hamish Robertson, *RPF* (Timberline) was the project manager and Hugh Carter, *MSc, RFT* (Timberline) completed the analysis and prepared the report. Chris Mulvihill, *RPF* (MFR) provided technical support during the design, implementation, and analysis phases of the projects. The results from this report will be reviewed and approved by the MFR Forest Analysis and Inventory Branch (FAIB) prior to use in TSR.

2.0 DATA

2.1 Land Base

The Invermere TSA is located within the Southern Interior Forest Region – Rocky Mountain District (Appendix I). The Rocky Mountain Forest District is situated in the southeast corner of BC and was created in 2003 by amalgamating the former Invermere and Cranbrook Forest Districts. The Invermere TSA covers approximately 1.12 million hectares of which approximately 458,000 ha (41%) are VT and > 30 years in 2007.

The Invermere TSA is located in the interior dry-belt of BC and contains six biogeoclimatic (BGC) zones. The BGC zones, in order of relative proportion are: Montane Spruce (MS), Englemann Spruce-Subalpine Fir (ESSF), Interior Douglas-fir (IDF), Interior Cedar-Hemlock (ICH), Ponderosa Pine (PP), and Alpine Tundra (AT). Lodgepole pine (Pl) and Douglas-fir (Fd) are the main species on the TSA, while interior spruce (Sx), western larch (Lw), and subalpine fir (Bl) are also important species. Minor species include ponderosa pine, western hemlock, western redcedar, whitebark pine, cottonwood, aspen, and birch. The age distribution is relatively uniform across all age classes.

2.2 Target Population

The target population was defined in 2007 using the TSA data obtained from the LRDW. The target population was identified as VT areas greater than or equal to 30 years in 2007. A depletion update was provided by Tembec that excluded all of Tembec's harvested areas up to September 2007.

The target population is 457,587 ha and represents approximately 41% of the total TSA area (Table 1).

Table 1. Invermere TSA net down.

Land Class	Area (ha)	% TSA
Total TSA	1,119,460	
Non-contributing	95,477	8.5%
Park	196,350	17.5%
Stands < 30 years	19,672	1.8%
Non Vegetated	254,282	22.7%
Non Treed	90,163	8.1%
Harvested	5,929	0.5%
Target Population	457,587	40.9%

2.3 Post-Stratification

The 2007 target population was stratified by pine, spruce, and Douglas-fir leading polygons in the operable area, and other areas in the target population not in the first three strata (including inoperable areas). The strata were then sub-stratified by age. Samples were selected and distributed using this stratification scenario.⁴

Approximately half of the population (54% or 247,595 ha) was located in stands within the Pine - Operable, Spruce - Operable, or Douglas-fir - Operable leading strata. Approximately 42% of the population (192,791 ha) in the first three strata was greater than 80 years. The Other stratum represents approximately 46% of the population with a majority greater than 140 years. Adjustment statistics were computed at the stratum level only; sub-strata were only used for sample selection.

Table 2. 2007 stratification scenario.

Stratum	Sub-Stratum	Area (ha)	% Pop.	% Stratum
Pine – Operable	30-80 yrs	33,562	7.3	31.6
	81-140 yrs	51,044	11.2	48.0
	141+ yrs	21,708	4.7	20.4
	<i>Sub-Total</i>	<i>106,313</i>	23.2	<i>100.0</i>
Douglas-fir – Operable	30-80 yrs	15,116	3.3	16.5
	81-140 yrs	42,283	9.2	46.1
	141+ yrs	34,420	7.5	37.5
	<i>Sub-Total</i>	<i>91,818</i>	20.1	<i>100.0</i>
Spruce – Operable	30-80 yrs	6,128	1.3	12.4
	81-140 yrs	7,497	1.6	15.2
	141+ yrs	35,839	7.8	72.5
	<i>Sub-Total</i>	<i>49,464</i>	10.8	<i>100.0</i>
Other – any areas not in strata 1-3	30-80 yrs	37,876	8.3	18.0
	81-140 yrs	55,603	12.2	26.5
	141+ yrs	116,513	25.5	55.5
	<i>Sub-Total</i>	<i>209,992</i>	45.9	<i>100.0</i>
<i>Total</i>		<i>457,587</i>	<i>100.0</i>	

Table 3. Invermere TSA photo-interpreted inventory statistics.

Stratum	Area (ha)	Height (m)	Age (yrs)	BA 7.5cm+ (m ² /ha)	SPH 7.5cm+ (trees/ha)	SI (m)	Vol. 12.5cm+ (m ³ /ha)
Pine – Operable	106,313	20.3	109	30.5	1,189	15.2	202.0
Douglas-fir – Operable	91,818	22.2	131	25.8	718	14.2	160.3
Spruce – Operable	49,464	25.6	191	34.0	753	11.6	265.0
Other	209,992	19.2	161	21.7	728	10.6	124.4
<i>Total</i>	<i>457,587</i>	<i>20.7</i>	<i>146</i>	<i>25.9</i>	<i>836</i>	<i>12.5</i>	<i>164.9</i>

⁴ Any polygon that was split by the operability line was deemed to be operable. This reassignment resulted in a shift in area from the Other strata into the other three strata and altered the area represented by each stratum and the selection weights used in this analysis.

2.4 Phase II (Ground Sampling)

2.4.1 Actual Sample Size

One hundred twenty (120) plots were selected for establishment. Samples located in harvested areas were replaced because a harvest depletion update was provided in September 2007.

Two samples were visited that had recently been harvested and these were replaced. Three samples were visited and considered unsafe, but were relocated using the MFR procedure for relocating unsafe samples. An additional sample was considered unsafe and not relocated as it posed minimal impact to the overall outcome (Table 4).⁵ Overall 119 samples were considered valid and used for this analysis (Appendix I, Figure 10).

2.4.2 Sampling Weights

The plots were initially selected in 2007. The Other stratum was intentionally under-sampled because it was of low interest in timber supply analysis. The weights were computed based on the distribution of the sample size, using 119 plots (Table 5). Sampling weights ranged from 2,043 ha to 12,625 ha or in relative terms from 1 to 6.2.⁶ The average weight was 3,845 ha/plot or 1.9 in relative terms. The sampling weight for each individual ground sample is provided in Appendix III.

2.4.3 Phase II Plot Statistics

The Phase II plot volumes were fairly consistent amongst all strata. Spruce volume contained the largest proportion of dead volume. The Pine - Operable and Douglas-fir - Operable strata had similar live and dead volumes. Site index was consistent over all strata with an overall average of 13.3m. (Table 6). The Pine - Operable stratum had the highest density and site index (15.3m). The Other stratum had the lowest average age, height, site index, and volume. Phase I and Phase II data is provided in Appendix IV.

Table 4. Plot distribution.

Land Class	No. Plots	(%)
Sampled Plots	120	100%
Harvested – not replaced	0	0%
Unsafe – not relocated	1	1%
Valid Plots	119	99%
Harvested – replaced	2	2%
Unsafe – relocated	3	3%
<i>Total</i>	<i>119</i>	<i>100%</i>

Table 5. Phase II Sampling weights.

Stratum	Sub-Stratum	Area (ha)	No. Plots	Area/Plot
Pine – Operable	30-80 yrs	33,562	15	2,237
	81-140 yrs	51,044	23	2,219
	141+ yrs	21,708	8	2,713
	<i>Sub-Total</i>	<i>106,313</i>	<i>46</i>	<i>2,311</i>
Douglas-fir – Operable	30-80 yrs	15,116	6	2,519
	81-140 yrs	42,283	19	2,225
	141+ yrs	34,420	12	2,868
	<i>Sub-Total</i>	<i>91,818</i>	<i>37</i>	<i>2,482</i>
Spruce – Operable	30-80 yrs	6,128	3	2,043
	81-140 yrs	7,497	3	2,499
	141+ yrs	35,839	12	2,987
	<i>Sub-Total</i>	<i>49,464</i>	<i>18</i>	<i>2,748</i>
Other	30-80 yrs	37,876	3	12,625
	81-140 yrs	55,603	5	11,120
	141+ yrs	116,513	10	11,651
	<i>Sub-Total</i>	<i>209,992</i>	<i>18</i>	<i>11,666</i>

⁵ Confirmed in discussions with Chris Mulvihill, RPF on July 2, 2008.

⁶ Relative weights are an expression of each weight compared to the minimum weight. Relative weights provide simple comparisons between substrata.

Table 6. Phase II plot statistics.

Stratum	n	Height (m)	Age (yrs)	BA (m ² /ha)	SPH (trees/ha)	SI (m)	Volume 12.5+ cm (m ³ /ha)		
							Live	Dead	Total
Pine – Operable	46	20.8	116	32.6	1,313	15.3	212.6	26.2	238.8
Douglas-fir– Operable	37	22.4	132	27.6	645	15.0	197.9	25.8	223.7
Spruce – Operable	18	23.7	155	31.1	846	13.6	230.0	37.7	267.7
Other	18	18.8	131	30.1	1,159	11.2	189.1	20.6	209.7
<i>Total</i>	<i>119</i>	<i>20.6</i>	<i>130.3</i>	<i>30.3</i>	<i>1,058</i>	<i>13.3</i>	<i>200.7</i>	<i>24.8</i>	<i>225.5</i>

Note: Phase II (ground sampling) volume was whole-stem volume less tops, stumps, NVAF-corrected cruiser-called decay, waste, and breakage.

2.5 NVAF

One hundred twenty (120) trees (110 live and 10 dead) were destructively sampled and used for the analysis (Table 7). Trees were selected by live / dead, maturity (Immature = 120 years, Mature > 120 years), and leading species. The “design-based” method was used for determining the ratios to account for the unequal distribution of plots within the TSA. The compiled NVAF tree data was provided by the MFR Volume and Decay Sampling Officer. Twenty (20) extra Pl trees were destructively sampled to obtain data to complete further analysis on small Pl taper. On average the NVAF volume was higher than the Phase II volume, meaning that the field samplers typically overstated the net factor. Overall the field samplers were reasonably accurate when net-factoring the trees (+0.3%), with the exception of the dead trees (-5.4%). The complete NVAF sample tree list is provided in Appendix II.

2.5.1 Small Pl Taper

As part of the NVAF program, the Invermere stakeholders sought data to support analysis of smallwood Pl taper against Provincial Pl taper equations. Forty-six (46) Pl trees (5 Dead, 25 Immature, and 16 Mature - Dead) were destructively sampled as part of the NVAF program and can be used for future analyses. If this issue is to be assessed further, the next step is to define the smallwood Pl population, determine the number of trees required for analysis, implement the program, and complete the analysis.

Table 7. NVAF tree summary statistics.

Live/ Dead	Maturity Class ⁷	Spp	No. Trees	Avg. Volume (m ³)		
				Phase II	NVAF	% Diff.
Dead	All	All	10	0.4863	0.4598	-5.4%
Live	Immature	All	43	0.2482	0.2532	2.0%
		Pl	16	0.3292	0.3328	1.1%
		Fd	22	0.4732	0.486	2.7%
		Sx	14	0.4401	0.4396	-0.1%
		Others	15	0.3205	0.3155	-1.6%
<i>All</i>			<i>120</i>	<i>0.6403</i>	<i>0.6428</i>	<i>+0.3</i>

⁷ Immature trees were all trees in polygons that had a stand age less than 121 years. All other trees were Mature.

3.0 METHODS

3.1 Phase I Projection

Photo-interpretation was done using photos taken in 1995. For this analysis the photo-interpreted age was projected to 2007 by adding the required number of years.⁸ The photo-interpreted height, basal area (BA), stems per hectare (SPH), and corresponding net merchantable volume were also projected to 2007 using VDYP7 (version 7.5c.27). VDYP7 does not project BA, SPH, or volume in cases where tree heights are less than 7.6 m. In these cases, polygons were assumed to have no volume, basal area and density. All other critical VDYP7 input (species composition, crown closure, forest inventory zone, inventory standard, and BEC) were not modified.

The data received from the LRDW included multiple records with the same feature_ID. The feature_ID is supposed to be a unique identifier for all VRI polygons in BC. To rectify this and to ensure proper areas were used, Timberline generated a unique ID for all polygons received from the LRDW that were used to define the target population.⁹

3.2 NVAF

The NVAF ratios were computed using the data received from the MFR. Ratios were computed using the design-based method (as per MFR request) and applied to the Phase II net merchantable volume computed from the raw data.

3.3 Phase II Compilation

The Phase II (ground sampling) data was compiled using the MFR SAS VRI Phase II compiler.¹⁰ The new compiler accounts for the inclusion of dead standing and fallen at the auxiliary plots. The plot data came in a raw form from the MFR as the cleaning routine is not functioning properly.¹¹ The data was checked using the VRI compiler error checking routines and other logic error checks throughout the analysis, however, only minor data entry errors were identified and fixed.

The GPS points were viewed in GIS to confirm that plots landed at the intended points. Three samples (samples 63, 94, and 97) were located in adjacent polygons, but in each case the differences between the intended and actual locations were so minor that they could be attributed to error in the GPS. The maximum difference between the intended coordinate and actual corrected coordinate was 6m. In all cases the intended polygon was used for analysis. The rationale for this is that the sample point location in the polygon is the audited step and not the GPS recording.

⁸ The majority of the Phase II plots (97 of 119 plots) were sampled in 2007 and the remainder sampled in 2008. As per MFR standards the data is projected to the year that the majority of sampling was completed.

⁹ The common records were combined to represent the total area of the polygon.

¹⁰ The compiler was received from the MFR on February 4, 2009.

¹¹ While we completed logical data checks Timberline assumes no responsibility for errors that would have been identified through the MFR data cleaning process.

3.4 Statistical Adjustment

The most recent MFR VRI statistical adjustment standards were used to adjust height, age, basal area (7.5+ cm), stems per hectare (7.5+ cm), and live net merchantable volume (12.5+ cm).¹² The MFR adjustment procedures assume that the unadjusted (Phase I) inventory volume is biased due to two sources of error:

1. An attribute bias associated with the photo-interpreted height, age, basal area, and stems per hectare; and
2. A model bias inherent to the growth and yield model used to estimate volume (VDYP7)¹³.

Three critical attributes needed for volume prediction are not adjusted in the process but are important for determination of other critical attributes. Inventory standard determines how basal area and stems per hectare are either used or generated, BEC zones are important for loss and are needed for every polygon, and species composition is used to distribute the volume.

The interim attribute adjustment procedure is a two-step process (Figure 2) described as follows:

- Step 1: Phase I height, age, basal area (7.5+ cm), and stems per hectare (7.5+ cm) bias are corrected using an adjustment ratio of means (ROM) calculated from the Phase I and Phase II plots. An attribute-adjusted volume is then estimated using VDYP7 with the adjusted height and age.
- Step 2: An adjustment ratio estimated from the attribute-adjusted volume (12.5+ cm) and the Phase II volume is calculated and this ratio is used to correct the model bias in the attribute-adjusted volume.

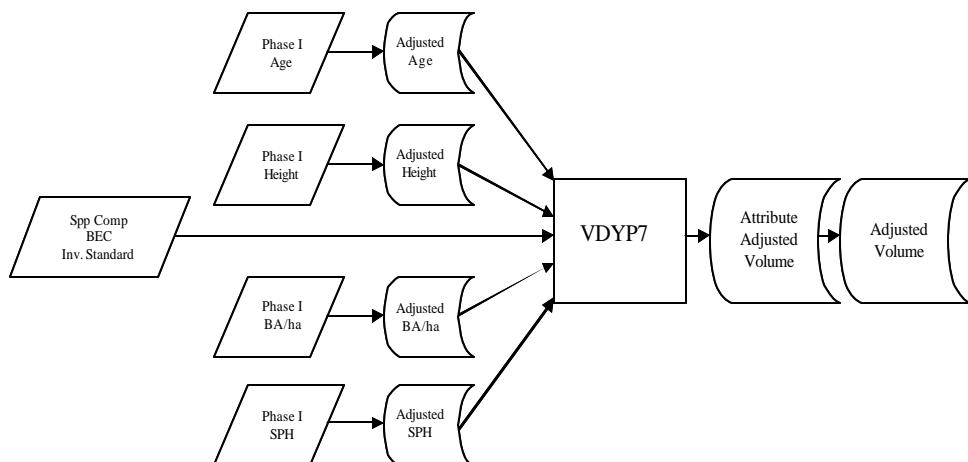

Figure 2. Interim procedures for adjustment of baseline VRI timber attributes.

¹² Ministry of Forests and Range. 2008. *Vegetation Resources Inventory Interim Procedures and Standards for Statistical Adjustment of Baseline VRI Timber Attributes*. Unpublished Report, January 2008. 36 pp.

¹³ VDYP7 is the new standard for growth and yield modeling in BC for unmanaged stands. All work prior to this adjustment was completed using VDYP6.

4.0 RESULTS

4.1 NVAF

The average NVAF ratio for live trees varied between 0.945 and 1.027 with an overall average of 1.005 (Table 8). The overall 95% sampling error (E%) for live trees was 3.0%. The remaining species groups were consistent and the sampling errors were relatively low with the Dead and Pl species group having higher sampling errors. The Fd – Operable stratum had the largest ratio (1.027), suggesting that the field samplers thought there was more decay in Fd than there actually was. Figure 3 illustrates the relationships between the cruiser called net factor and the destructively sampled trees for each species group.

Table 8. NVAF ratios.

Live/ Dead	Maturity	Spp	No. Trees	Ratio	95% E%
Dead	All	All	10	0.945	14.1%
Live	Immature	All	43	1.020	4.9%
	Mature	Pl	16	1.011	11.4%
		Fd	22	1.027	6.3%
		Sx	14	0.999	7.8%
		Others	15	0.984	8.6%
	<i>All</i>	<i>All</i>	120	1.005	3.0%

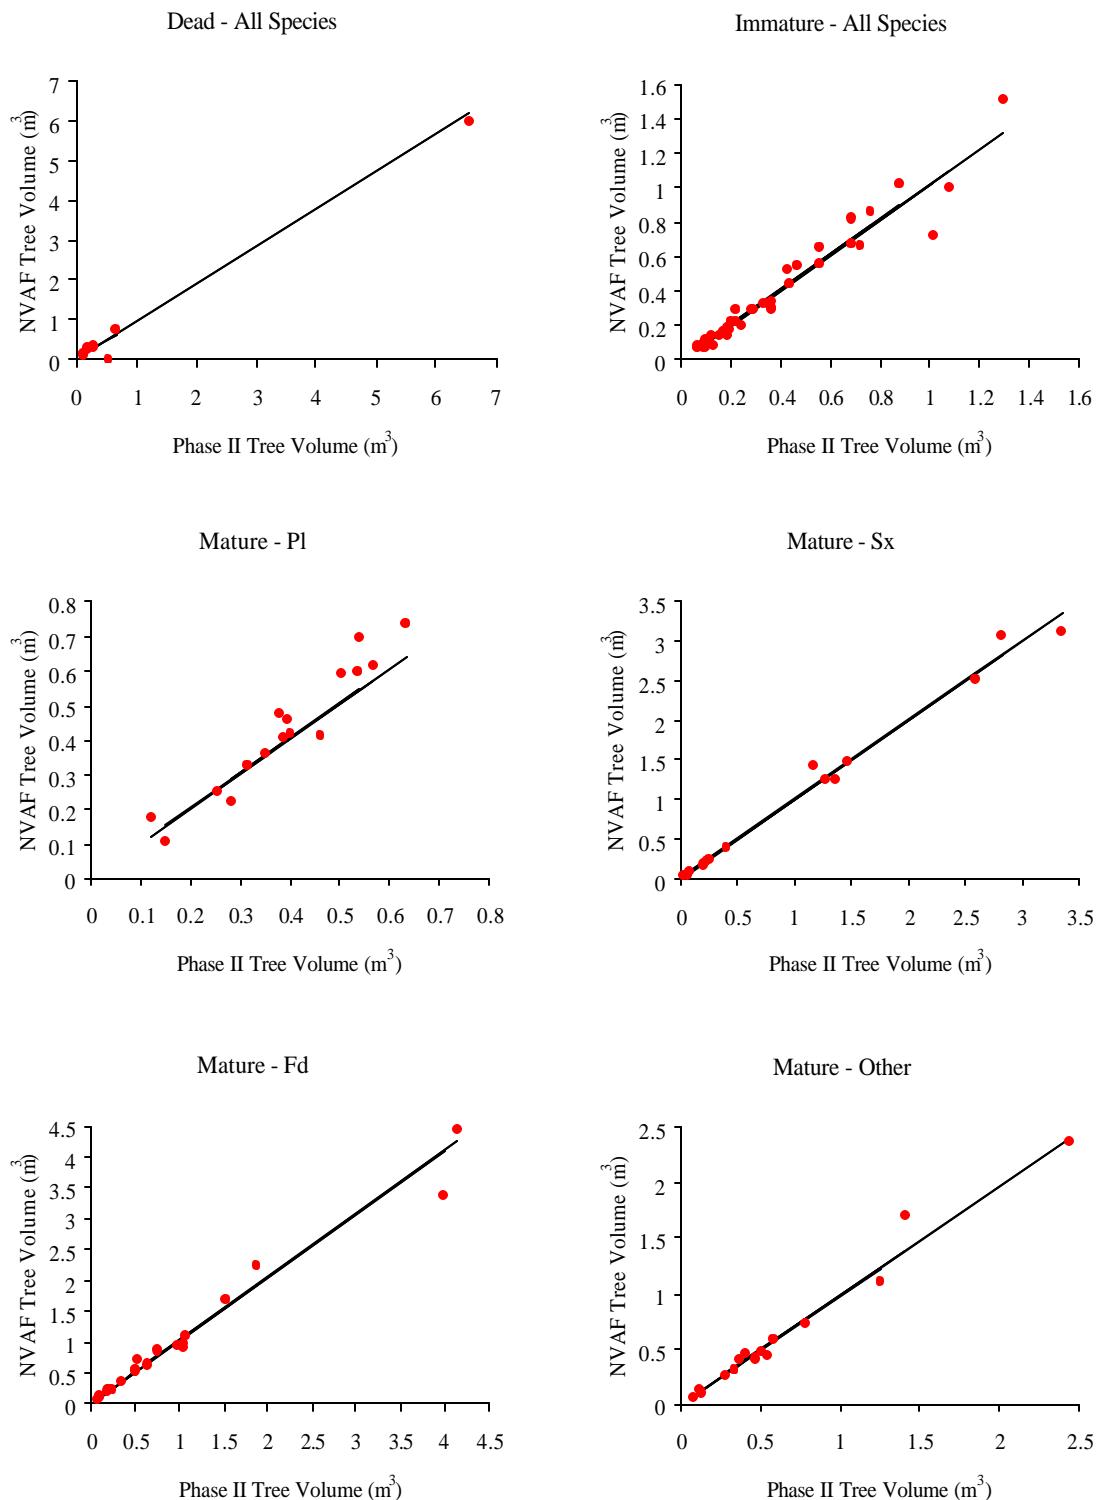

Figure 3. NVAF scatterplots.

4.2 Height

Six plots had no suitable height observation, leaving 113 plots for analysis. On average, height was over-estimated by approximately 5% with a sampling error of $\pm 6\%$ (95% probability) (Table 9, Figure 4). The sampling error of the adjustment ratio was particularly high in the Other stratum, which has a low number of observations.

Table 9. Height adjustment statistics for the target population.

Stratum	Unadjusted Pop.		Sample			ROM	Adjusted. Population	
	Area (ha)	Avg. (m)	n	Phase I (m)	Phase II (m)		Adj. Avg. (m)	95% E (m)
Pine – Operable	106,313	20.3	45	21.3	20.8	0.977	19.8	1.2
Douglas-fir– Operable	91,818	22.2	35	23.1	22.4	0.970	21.6	1.8
Spruce – Operable	49,464	25.6	17	26.0	23.7	0.912	23.3	2.9
Other	209,992	19.2	16	20.1	18.8	0.935	17.9	2.5
<i>Total</i>	<i>457,587</i>	<i>20.7</i>	<i>113</i>	<i>21.6</i>	<i>20.5</i>	<i>0.949</i>	<i>19.7</i>	<i>1.2</i>
								<i>6.2</i>

4.3 Age

Four (4) plots had no suitable age observation, leaving 115 plots for analysis. Phase I age was over-estimated on average by approximately 6% with a sampling error of $\pm 9.5\%$ (95% probability) (Table 10, Figure 5). Age in the Spruce - Operable stratum was over-estimated by almost 14% with a $\pm 20\%$ sampling error (95% probability). The overall sampling error was relatively low at approximately 10%.

Table 10. Age adjustment statistics for the target population.

Stratum	Unadjusted Pop.		Sample			ROM	Adjusted Pop.	
	Area (ha)	Avg. (yrs)	n	Phase I (yrs)	Phase II (yrs)		Adj. Avg. (yrs)	95% E (yrs)
Pine – Operable	106,313	109	45	110	116	1.056	115	13
Douglas-fir– Operable	91,818	131	35	135	132	0.975	128	17
Spruce – Operable	49,464	191	18	181	155	0.860	164	33
Other	209,992	161	17	144	131	0.912	147	27
<i>Total</i>	<i>457,587</i>	<i>146</i>	<i>115</i>	<i>138</i>	<i>130</i>	<i>0.941</i>	<i>137</i>	<i>13</i>
								<i>9.5</i>

4.4 Basal Area

All 119 plots were used for the basal area analysis. Phase I basal area was underestimated on average by approximately 8% (Table 11, Figure 6) with a 10.9% (95% probability) sampling error. Basal area was underestimated in the Other stratum by approximately 24%. The Spruce – Operable stratum Phase I basal area was over-estimated on-average by approximately 8% with a sampling error of approximately $\pm 29\%$. The results suggest that basal area generated by VDYP7 in the Spruce – Operable stratum has relatively low precision, which could be due to poor inventory values used for generating basal area estimates.

Table 11. Basal area adjustment statistics for the target population.

Stratum	Unadjusted Pop.		Sample			Adjusted Pop.		
	Area (ha)	Avg. (m ² /ha)	n	Phase I (m ² /ha)	Phase II (m ² /ha)	ROM	Adj. Avg. (m ² /ha)	95% E (m ² /ha) (%)
Pine – Operable	106,313	30.5	46	31.9	32.6	1.022	31.2	3.9 12.4

4.5 Stem Per Hectare

All one-hundred nineteen (119) plots were used for the SPH analysis. Phase I SPH was under-estimated on average by approximately 12% with a sampling error $\pm 18.5\%$ (95% probability) (Table 12, Figure 7). SPH was over-estimated in the Douglas-fir – Operable stratum by approximately 15%. All other strata were under-estimated for stems per hectare in the Phase I. The most variable stratum was the Other stratum with a sampling error of approximately $\pm 41\%$ (95% probability).

Table 12. Stems per hectare adjustment statistics for the target population.

Stratum	Unadjusted Pop.		Sample			ROM	Adjusted Pop.		
	Area (ha)	Avg. (SPH)	n	Phase I (SPH)	Phase II (SPH)		Adj. Avg. (SPH)	95% E (SPH) (%)

4.6 Input-adjusted VDYP7 Volume

After adjusting the bias in height, age, basal area, and SPH, VDYP7 volumes were re-estimated using the adjusted input. Attribute-adjusted volumes showed no appreciable change at the 12.5cm+ levels when compared to the Phase I volumes (Table 13). These metrics are for comparison purposes only and do not have any impact on the outcome of the analysis.

Table 13. Volume change due to input attribute adjustment.

Stratum	Area (ha)	Volume (m ³ /ha) 12.5cm+			Diff. (m ³ /ha)	(%)
		Phase I	Attribute- Adjusted			
Pine – Operable	106,313	202.0	196.6	-5.4	-2.7%	
Douglas-fir– Operable	91,818	160.3	155..0	-5.3	-3.3%	
Spruce – Operable	49,646	265.0	221.1	-43.9	-16.6%	
Other	209,992	124.4	139.7	15.3	12.3%	
<i>Total</i>	<i>457,587</i>	<i>164.8</i>	<i>164.8</i>	<i>0.0</i>	<i>0.0%</i>	

4.7 Live Net Merchantable Volume

The overall live net merchantable volume increased by 12% following adjustment (Table 14, Figure 8) with a ±13% overall sampling error (95% probability). The average adjusted live volume/ha was approximately 185 m³/ha. The sampling error for the Spruce – Operable stratum was approximately 36% and could reflect the variable basal area predictions generated from VDYP.

Table 14. Live net merchantable volume (12.5cm+) adjustment statistics.

Stratum	Attr. Adj. Vol.		Sample				Adjusted Population		
	Area (ha)	Avg. (m ³ /ha)	n	Phase I (m ³ /ha)	Phase II (m ³ /ha)	ROM	Adj. Avg. (m ³ /ha)	(m ³ /ha)	(%)
Pine – Operable	106,313	196.6	46	214.0	210.2	0.982	193.1	32.4	16.8
Douglas-fir– Operable	91,818	155.0	37	180.2	196.5	1.090	169.0	35.6	21.0
Spruce – Operable	49,646	221.1	18	229.9	230.7	1.003	221.9	80.7	36.4
Other	209,992	139.7	18	149.2	190.6	1.278	178.6	47.9	26.8
<i>Total</i>	<i>457,587</i>	<i>164.8</i>	<i>119</i>	<i>179.2</i>	<i>200.7</i>	<i>1.121</i>	<i>184.7</i>	<i>24.4</i>	<i>13.2</i>

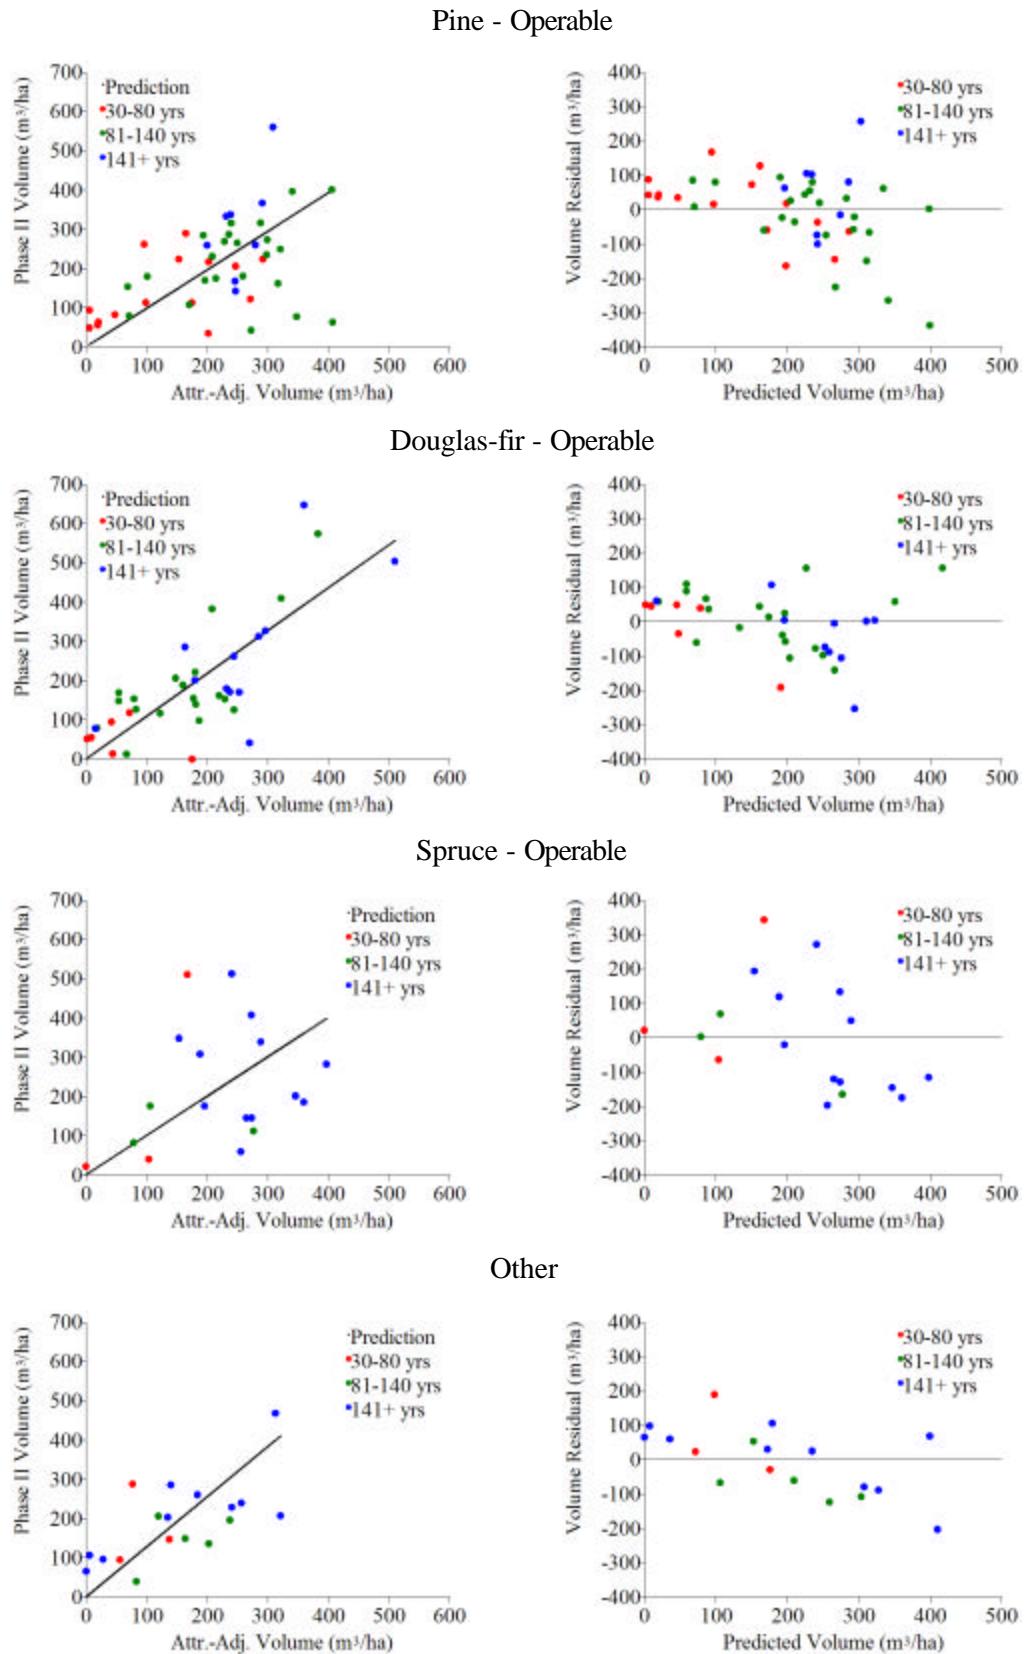

Figure 8. Live volume (12.5+ cm) scatterplots.

4.8 Site Index

Site index is not directly adjusted in the VRI standard statistical adjustment. Instead, an adjusted site index is derived from adjusted height and age. The inventory site index decreased by approximately 2.5% after adjustment (Table 15). The decrease was largest in the Pine – Operable stratum at -5.1%. This is consistent with the height in this strata decreasing and the age increasing in this stratum.

Table 15. Site index change after adjustment.

Stratum	Area (ha)	Phase I SI (m)	Adj. SI (m)	Difference (%)
Pine – Operable	106,313	15.2	14.5	-5.1%
Douglas-fir – Operable	91,818	14.2	14.0	-1.6%
Spruce – Operable	49,464	11.6	11.4	-1.6%
Other	209,992	10.6	10.4	-1.7%
<i>Total</i>	<i>457,587</i>	<i>12.5</i>	<i>12.2</i>	<i>-2.6%</i>

4.9 Coarse Woody Debris

Coarse woody debris (CWD) was collected at each sample to derive a broad indication of the volume of down dead wood (by species) currently in the Invermere TSA. All 119 samples were used for the summary excluding any accumulations encountered in the field sampling (Table 16). Overall the Spruce - Operable stratum had the largest amounts of CWD ($117.4 \text{ m}^3/\text{ha}$). Overall, Xc (unknown conifer) pieces made up the majority of volume followed by Pl. As expected, the variability around the volumes was quite high which suggests that these estimates should only be used as broad indications of down dead wood. If management decisions related to CWD were required, more samples or different procedures are required to achieve a level of comfort for each stratum.

Table 16. Summary of CWD volume.

Stratum	Area (ha)	Plots	Volume (m^3/ha)							
			B	Fd	Pl	Sx	Xc	Decid	Other	Total
Pine – Operable	106,313	46	2.4	3.8	26.7	3.0	67.5	0.6	8.3	112.2
Douglas-fir – Operable	91,818	37	1.7	14.8	9.1	2.5	21.4	1.3	3.3	54.1
Spruce – Operable	49,464	18	17.3	0.8	14.2	18.6	62.0	0.3	4.3	117.4
Other	209,992	37	6.0	5.2	25.9	7.8	53.2	0.3	2.8	101.2
<i>Total</i>	<i>457,587</i>	<i>119</i>	<i>5.8</i>	<i>6.5</i>	<i>21.6</i>	<i>7.2</i>	<i>52.9</i>	<i>0.6</i>	<i>4.5</i>	<i>99.0</i>

4.10 Forest Health

Forest health is a significant management consideration for the Invermere TSA stakeholders. Forest health data is collected in Phase II sampling and provides a broad indication of the occurrence of forest health indicators on the landbase. Each sample is a random point (representing approximately 3,845 ha not weighted by strata areas) within the target population and together the samples cover a range of variability in the TSA. Table 17 shows the presence of forest health indicators within Invermere TSA. Each occurrence is the equivalent to the presence

of at least one tree within a plot being affected by one of the damage agents.¹⁴ This table represents only a summary of forest health indicators (with no precision) within the TSA and should not be used for management decisions; however this information can be used as a guide for further work to obtain more detailed information.

Insects had the highest incidence of any important damage agent. Thirty-eight (38) of the 119 samples had at least one tree with an insect identified by the field samplers (approximately 32%). Twelve (12) samples had MPB identified and of these twelve, five samples were in the Pine – Operable stratum, meaning that approximately 11% of samples in this stratum were affected by MPB. Windthrow¹⁵ also had considerable occurrence within the TSA where 23 of the 119 samples (approximately 19% of the samples) had windthrow identified by the field samplers.

Table 17. Presence of damage agents.

Damage Agent	Occurrences in Samples (n)	% of Samples with Occurrence
Scarring	44	37
Insects	38	32
Aphids	17	14
Bark beetles	19	16
Windthrow	23	19
Fire Damage	18	15
Animal	16	13
Stem Disease	16	13
Dwarf Mistletoe	11	9
Stem Rot	8	7
Frost Damage	8	7
Mechanical	5	4
Root Disease	3	3
Snow or Ice	2	2
Broom Rust	1	1
Slide Damage	1	1

¹⁴ It is possible that one tree could be exhibiting all the occurrences of damage agents within that plot. This is only a summary and further work could be completed if more detailed information is required.

¹⁵ It is possible that one forest health indicator is the result of another. For example windthrow could be a result of trees being infected by diseases or insects.

5.0 DISCUSSION

5.1 Sample vs. Population

A sample must adequately cover the range of Phase I values in the population to avoid extrapolating information to areas that were not sampled (given that all polygons had a chance of being sampled). We expect that a minimal amount of extrapolation will be required with a random sample since the minimum and maximum values observed in the population will not always be included in the sample. With a random sample of size n, one would expect on average that 100%/2n of the population is below or above the minimum or maximum observed in the sample.

Table 18. Population outside of the sampled range.

Stratum	Expected Proportion	Age		Height		Volume	
		Below	Above	Below	Above	Below	Above
Pine – Operable	1.1	1.2	0.0	0.2	0.0	0.0	0.1
Douglas-fir– Operable	1.4	0.5	0.1	0.1	0.0	0.0	0.2
Spruce – Operable	2.8	1.7	1.7	2.3	1.1	0.0	0.4
Other	2.8	0.3	0.8	1.4	0.1	0.0	0.0

Overall only small portions of area were outside of the expected proportion for all attributes for all variables (Table 18). The largest amount of area not covered in the range of sampling was the below height category for the Spruce – Operable stratum (2.3%). For all areas that are outside of the sampled area there is the potential for biased estimates of those attributes as they were extrapolated. The risk is low in the Invermere TSA as the amount of area above or below the range of attributes are all within the expected proportions.

5.2 Accuracy and Precision

The statistical adjustment provides unbiased estimates at the scale in which the ratios were computed. In the case of the Invermere TSA, unbiased estimates will be at the stratum level. There is always a possibility that local bias exists within a stratum. It would be inappropriate to estimate sub-stratum bias given the small sample size provided at a smaller scale.

The MFR-recommended precision for adjusted average volume at the management unit level is a sampling error of $\pm 10\%$ (95% probability). The overall sampling error achieved in this project was $\pm 13\%$ (95% probability).

5.3 Impact of Change

5.3.1 Live Volume

The overall live volume increased by about 12% following adjustment (Table 19). The increase in live volume is most prevalent in the Other stratum which increased by approximately $54 \text{ m}^3/\text{ha}$. This stratum is of little interest in timber supply and carried significant weight in the overall average due to the area occupied. There was a relatively large decrease in basal area for the Spruce – Operable stratum which likely

strongly impacted the volume estimates derived from VDYP7. The impact of change between the Phase II ground volumes and the attribute adjusted volume is negligible with a decrease in attribute adjusted volume of approximately 4%, indicating that in general, VDYP7 adequately predicted volume in the target population with the adjusted input attributes.

5.3.2 Age

The age adjustment had little impact on the age class distribution (Figure 9). The result was more slightly area in age classes 2, 3 and 5 and less area in age classes 4 and 9. This is confirmed by the relatively small adjustment made overall. Age class 2 covers the range of 21-50 and this figure only includes area for ages 30 and above as defined in the target population.

Table 19. Volume change after adjustment.

Stratum	Area (ha)	Volume 12.5cm + (m ³ /ha)		Difference	
		Phase I	Adjusted	(m ³ /ha)	(%)
Pine – Operable	106,313	202.0	193.1	-8.9	-4.4%
Douglas-fir – Operable	91,818	160.3	169.0	8.7	5.4%
Spruce – Operable	49,464	265.0	221.8	-43.2	-16.3%
Other	209,992	124.4	178.6	54.2	43.6%
Other - Operable	39,855	121.1	173.2	52.1	43.0%
Other - Inoperable	170,137	138.6	201.6	63.0	45.5%
<i>Total</i>	<i>457,587</i>	<i>164.9</i>	<i>184.7</i>	<i>19.8</i>	<i>12.0%</i>

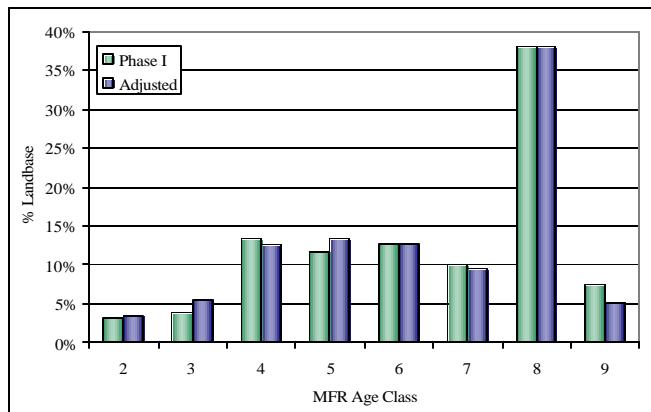

Figure 9. Change in MFR age class.

5.4 Risks and Uncertainties

5.4.1 Spruce – Operable Stratum

The Spruce - Operable stratum (11% of the target population) volume sampling error was $\pm 36\%$ (95% probability). This high variability is likely due to the low number of observations (18) and VDYP7's ability to generate reliable basal area estimates, which is significant for volume estimation.

5.4.2 Age Trend

The statistical adjustment removes the bias in each stratum. It is possible that an age-related trend exists within each stratum. All residuals were plotted against stand age to detect any age-related trend. Age in the Other stratum and stems per hectare in the Spruce – Operable stratum showed

slight age related trends, but are of minor concern. Volume is the most important attribute and there were no age correlations in any stratum.

6.0 CONCLUSIONS

After adjustment, live net merchantable volume increased by 24m³/ha (or 12%). Height and age decreased by 5% and 6%, respectively, and basal area and stems per hectare increased by 8% and 12%, respectively. Site index decreased by 3%.

As discussed, the main source of uncertainty in the inventory is the Spruce – Operable stratum; however it is expected that this is of marginal importance in timber supply analysis. The overall volume statistics were $\pm 13\%$ (95% probability) which is greater than the anticipated target sampling error of $\pm 10\%$ (95% probability).¹⁶ This is likely due to the use of basal area and stems per hectare in VDYP as these attributes exhibited relatively large variability in the TSA. If the TSA stakeholders are concerned about the relatively high sampling errors in the Spruce – Operable and Other strata they should consider installing more samples in an attempt to bring the sampling error to an acceptable level.

6.1 Recommendations

Unbiased estimates of height, age, basal area, stems per hectare, and volume were obtained using the MFR's VRI statistical adjustment standard methods. These estimates represent the best available inventory estimates. Therefore, we recommend that:

MFR use the adjusted estimates of height, age, basal area, stems per hectare, and volume in the timber supply analysis base case.

The NVAF destructive sample was intended to obtain some of the data required to properly investigate how well the Provincial Pl taper equations fit small Pl. Therefore, we recommend that:

The stakeholders use the Pl NVAF data together with other destructively sampled Pl tree data to assess possible taper issues in the small Pl population of interest.

The data collected for CWD and forest health information could provide insight to particular forest health issues with a presence within the TSA. Therefore, we recommend that:

The stakeholders consider the CWD and forest health statistics provided in this report as a starting point for investigating specific CWD and forest health issues.

The new inventory data provides a rich set of information that can be used for a variety of broad scale strategic planning. Therefore, we recommend that:

The stakeholders use the adjusted inventory for forest management planning.

¹⁶ The sample design was completed using VDYP6 and the adjustment was completed using VDYP7. One of the key differences between the two models is that basal area is a key factor in deriving volume estimates in VDYP7, whereas it is not used in VDYP6. The differences between models may partly explain why this project did not achieve the target sampling error.
