British Columbia Greenhouse Gas Offset Protocol: Forest Carbon

Version: 2.0

Director
Greenhouse Gas Industrial Reporting and Control Act

[DATE TBD], 2021

SUMMARY OF REVISIONS

VERSION	DATE	DESCRIPTION
1.0	July 2011	Original version.
-	June 2016	Removed from approved protocol list.
2.0	[DATE TBD] 2021 (draft)	<ul style="list-style-type: none"> • Definitions added • Extraneous guidance reduced • Protect types modified to the following: <ol style="list-style-type: none"> 1. Afforestation / Reforestation 2. Conservation / Improved Forest Management 3. Avoided Conversion • Baseline Scenario approach more specific • Modelling requirements more specific • Emission factors and parameter constants updated • Carbon pools renamed as carbon Reservoirs • Some SSRs eliminated or consolidated • Harvest-shifting Leakage factors updated • Requirement for a Monitoring and Maintenance Plan. • Contingency Account and Risk of Reversal requirements added

107

1.0 GUIDANCE

108

109 The purpose of the British Columbia (B.C.) Greenhouse Gas Offset Protocol for the Creation of
110 Forest Carbon Offsets (the Protocol) is to quantify Greenhouse Gas (GHG) Emission Reductions
111 and carbon dioxide (CO₂) Removal Enhancements by Sinks and Reservoirs of carbon. Failure to
112 comply with this Protocol or requirements of the *Greenhouse Gas Industrial Reporting and Control*
113 *Act* or Greenhouse Gas Emission Control Regulation may result in a Project Plan not being
114 accepted, or offset units not being issued.

115

116 The Protocol has the effect of a regulation.

117

118 The Project Proponent is responsible to ensure the Validation Body selected for a Project using
119 this Protocol is accredited by the Standards Council of Canada Technical Sector C: GHG
120 Emission Reductions & Removals from Agriculture, Forestry & Other Land Use (AFOLU), or by
121 the American National Standards Institute Sector for Group 3: Land Use, Land Use Change, &
122 Forestry.

123

124 The Project Proponent is responsible to provide justification where any assumptions or estimates
125 are used in the Project Plan.

126

127 The Project Proponent is responsible to ensure the requirements of the Protocol, the *Act*, and
128 Regulations are met, and required forms are complete.

2.0 DEFINITIONS AND ABBREVIATIONS

2.1 DEFINITIONS

In the Protocol, the capitalization of terms where the capitalization is not performing a grammatical function indicates a defined term in either the Regulation or this section.

“**Act**” means the *Greenhouse Gas Industrial Reporting and Control Act*.

“**Afforestation**” means activities that meet the criteria defined in Section 3.2.1.

“**Atmospheric Benefits**” mean entitlements and/or Offset Units generated from Projects where there are property rights, contractual rights, or right of access to those entitlements and/or Offset Units.

“**Avoided Conversion**” means activities that meet the criteria defined in Section 3.2.3.

“**Baseline**” refers to the Greenhouse Gas Emissions generated and activities on the proposed Project Site that would most likely occur in the absence of a proposed Project.

“**Baseline Emissions**” means the amount of Greenhouse Gas Emissions, established by, or estimated in accordance with, the Protocol that would occur from all selected Sources were the Project not carried out.

“**Baseline Removals**” means amount of Greenhouse Gas, established by, or estimated in accordance with, the Protocol that would be removed from the atmosphere by all selected Sinks were the Project not carried out.

“**Baseline Scenario**” means a hypothetical reference case that best represents the conditions most likely to occur in the absence of a proposed Project.

“**Biomass**” means non-fossilized plants or parts of plants, animal waste, or any product made of either of these and includes, without limitation, Biomass derived fuels, wood and wood products, agricultural residues and wastes, biologically derived organic matter found in municipal and industrial wastes, black liquor, kraft pulp fibres and sludge gas.

“**Contingency Account**” means an account managed by the Director where, as specified in the protocol, up to 51% of Offset Units issued in relation to a sequestration Project or storage Project must be credited.

“**Conservation**” means activities that meet the criteria defined in Section 3.2.2.

“**Crown land**” means land, whether or not it is covered by water, or an interest in land, vested in the government.

171 **"Crediting Period"** refers to the 25-year period through which the Primary Activity occurs, and
172 when Project Emission are determined.
173

174 **"Director"** means the government employee designated in writing by the minister as Director for
175 the purposes of the *Greenhouse Gas Industrial Reporting and Control Act*.
176

177 **"Emissions"** means Greenhouse Gases.

178 **"Emission Reductions"** means Baseline Emissions minus Project Emissions.
179

180 **"Forest land"** means an area:
181 • That is greater than or equal to one hectare in size measured tree-base to tree-base
182 (Stand-Alone to Stand-Alone), and
183 • Where trees on the area are capable of achieving:
184 1. A minimum height of 5 metres at maturity, and
185 2. A minimum crown cover of 25% at maturity.

186 **"Greenhouse Gases"** means carbon dioxide, methane, and/or nitrous oxide, measured in metric
187 tonnes of carbon dioxide equivalent.

188 **"Harvest-shifting Leakage"** (also known as market Leakage) means the increase in
189 Greenhouse Gas Emissions that occur from outside the Project Site as a result of reduced
190 production of a commodity, causing a change in the supply and market demand equilibrium that
191 results in a shift of production elsewhere to make up for the lost supply.

192 **"Harvested Wood Products"** means all wood material (including bark) that leaves harvest sites.

193 **"Improved Forest Management"** means activities that meet the criteria defined in Section 3.2.2.

194 **"Land Use-shifting Leakage"** (also known as activity-shifting Leakage) means the increase in
195 Greenhouse Gas Emissions that occur from outside the Project Site as a result of the Primary
196 Activity, and see conversion of Forest land shifting to other lands owned or controlled by the
197 Project Proponent due to the Project.

198 **"Leakage"** means the increase in Greenhouse Gas Emissions that occur from outside the Project
199 Site as a result of the Primary Activity.

200 **"Materiality Threshold"** means a quantitative threshold for verification purposes where the
201 aggregate or individual effects of errors, omissions or misrepresentations could have resulted in
202 an overestimation of Project Reductions by more than 5%, except where stated otherwise for the
203 purposes of quantifying and sampling the Baseline and Project Emissions and Reservoir.

204 **"Monitoring"** means the continuous or periodic assessment and documentation of GHG
205 Emissions and Removals or other GHG-related data.

206 **"Monitoring Period"** means the 100-year period through which a Project Proponent must ensure
207 Emission Reductions and Removal Enhancements are Permanent.
208

209 **"Offset Units"** means one verified tonne of Emissions reduction or Removal achieved as part of
210 and in accordance with an accepted Emission offset Project in respect of which the Director has
211 received a report of the outcome of the Project and a verification statement in relation to the report.
212

213 **"Performance Standard"** means either a technical, activity or performance measure used to
214 establish the Baseline Scenario, and determine Baseline Emissions or a component of Baseline
215 Emissions, identified in Section 5.1.

216 **"Permanent"** means the sequestration of Greenhouse Gases for a 100-year period following the
217 Crediting Period.

218 **"Primary Activity"** means the main activity or set of activities in the Project Scenario that result
219 in the majority of Emission Reduction from the Baseline Scenario.

220 **"Program of Activities"** means a type of Project that is not Stand-Alone where a group of similar
221 Project Instances are covered by a single Project Plan and additional Project Instances may be
222 added to the Project over the course of the Project Crediting Period.

223 **"Project"** means a Greenhouse Gas reduction Project as described in the Project Plan.
224

225 **"Project Emissions"** means:

- 226 • In relation to a Project Plan, the amount of Greenhouse Gas Emissions, estimated in
227 accordance with the applicable Protocol, that would occur from all selected Sources were
228 the Project carried out; and
- 229 • In relation to a Project Report, the amount of Greenhouse Gas Emissions, determined in
230 accordance with the Project Plan, that occurred from all selected Sources in the Project
231 Report Period.
232

233 **"Project Instance"** means, in relation to a Program of Activities, a single instance of a Project
234 Scenario that, in combination with other Project Instances, is covered by the same Project Plan.

235 **"Project Plan"** means a plan prepared in accordance with Section 14 of the Regulation (Project
236 Plans).

237 **"Project Proponent"** means a person or organization who submits to the Director, directly or
238 though a validation body, a plan for an Emission offset Project that the person proposes to or
239 does carry out. The Project Proponent also refers to any non-controlling shareholder that directs
240 or partially directs day-to-day operations or reporting.

241 **"Project Reduction"** means the total of the Emissions Reduction and the Removals
242 Enhancement, less any discounts applied in accordance with the Protocol, that are estimated to
243 occur or that have occurred in the Crediting Period and Monitoring Period.

244 **"Project Removals"** means:

- 245 • In relation to a Project Plan, the amount of Greenhouse Gases estimated in accordance
246 with the Protocol that, were the Project carried out, would be removed by all selected
247 Sinks; and
- 248 • In relation to a Project Report, the amount of Greenhouse Gas, determined in accordance
249 with the Project Plan, removed by all selected Sinks in the Project Report Period.

250 **"Project Report"** means a report described in the Regulation that meets the prescribed
251 requirements of both the Regulation and the Protocol for each Project Report Period.

252 **"Project Report Period"** means, each period for which a separate Project report is or must be
253 prepared.

254 **"Project Scenario"** means the activities taken by the Project Proponent that reduce or remove
255 greenhouse gas emissions and constitute the estimation of the Project Emissions.

256 **"Project Site"** means the physical footprint where the Primary Activity occurs.

257 **"Project Specific"** means an approach to establish the Baseline Scenario that is specific to the
258 Project.

259 **"Protocol"** means the Forest Carbon Offset Protocol Version 2.0 (FCOP).

260 **"Reforestation"** means activities that meet the criteria defined in Section 3.2.1.

261 **"Regulation"** means Greenhouse Gas Emission Control Regulation.
262

263 **"Removal"** means an amount of Greenhouse Gas that is removed from the atmosphere by an
264 industrial or biological process and stored or sequestered, or components of which are stored or
265 sequestered in a Reservoir.
266

267 **"Removal Enhancement"** means Project Removals minus Baseline Removals.
268

269 **"Reservoir"** means a physical unit, or component of the biosphere or geosphere, that has the
270 capability to store or accumulate Greenhouse Gas, or a component of Greenhouse Gas, removed
271 from the atmosphere
272

273 **"Reversal"** means any events that results in a loss of more than five percent of carbon stocks in
274 Reservoirs included in the Project Site, but has not been taken into account of projected Removal
275 Enhancements in the Project Plan.
276

277 **"Risk of Reversal"** means a risk factor addressed in Section 8.4.5.2 and determined in Appendix
278 H that represents the magnitude and likelihood that a Reversal will occur up to 100 years after
279 the Crediting Period ends
280

281 **"Risk Mitigation Measures"** mean the Project-specific actions or attributes undertaken in
282 Appendix H that reduce the overall Risk of Reversal for a Project.
283

284 **"Sink"** means a physical unit or process that removes Greenhouse Gas from the atmosphere.
285

286 **"Source"** means any process or activity through which a GHG is released into the atmosphere.
287

288 **"Stand-Alone"** means a type of Project where all the Instances of the Primary Activity occur on
289 the Project Site of the Project Scenario, and are identified in the validated Project Plan.
290

291 **2.2 ABBREVIATIONS AND ACRONYMS**

292	"AAC"	Annual Allowable Cut
293	"AC"	Avoided Conversion
294	"AFF"	Afforestation
295	"AFOLU"	Agriculture, Forestry and Other Land Use

438
439
440
441
442

The following general criteria must be met for Projects:

1. The Primary Activity of the Project Scenario must meet at least one of the definitions and specific eligibility criteria under Sections 3.2.1, 3.2.2, or 3.3.3.
2. For Crown lands:
 - a. The Project Proponent must have authority to access and use Crown land (i.e. a tenure, Land Use Agreement, Master Licence of Occupation) for the purpose of developing a Forest Carbon Emission Offset Project, and entitlement to the Atmospheric Benefits for the duration of the Crediting Period and Monitoring Period,
 - b. The Project must use genetically diverse and productive seed stock, wherever planting activity happens in Crown lands, and is expected to apply the current version of B.C. Chief Forester's Standards for Seed Use, which prohibit the use of genetically modified trees and limit the use of species collected outside of B.C.,
 - c. The Project Proponent shall conduct a local stakeholder and/or community engagement prior to validation as a way to inform the design of the project and maximize community participation. The Project Proponent shall establish mechanisms for ongoing communication with the local community to allow individuals or organizations to raise concerns about potential negative impacts during Project implementation. Further, the Project Proponent shall take due account of all and any input retrieved during engagement, and must either incorporate into Project design (with documentation) or justify why updates are not appropriate.
3. For privately-held land, the Project Proponent must provide:
 - a. Proof of fee-simple ownership for duration of the Crediting Period and Monitoring Period.
4. The Project Proponent is required to disclose in writing to the Validation Body / Verification Body any and all instances of non-compliance with any legal or regulatory requirement associated with Project lands in B.C. or Canada.
5. None of the Project Reductions result from reductions in GHGs other than CO₂, CH₄ and N₂O.
6. The Project Proponent, Validation Body, and Verification Body must all have a Registered Professional Forester (RPF) on their project teams. The RPF must be accredited with the Association of BC Forest Professionals for practice in B.C., and must have credentials that are pertinent to the Project as defined by the *Forester's Act*.

443

3.2 PROJECT TYPES

444
445
446
447

Project Proponents may select from the three Project types below.

448 **3.2.1 Afforestation / Reforestation**

449 **Project Type Definition:**

450
451 Afforestation (AFF) is defined as the direct human-induced conversion of land that has not been
452 Forest land for at least 20 years prior to Project commencement to Forest land through planting,
453 seeding and/or human-induced promotion of natural seed Sources. Areas suitable for AFF
454 Projects include, but are not limited to:

- 455 • Marginal productivity land,
- 456 • Urban land,
- 457 • Agricultural land, or
- 458 • Degraded industrial lands.

459 Reforestation (REF) is defined as the re-establishment of trees through planting, seeding and/or
460 human-induced promotion of natural seed sources on land that has been Forest land within the
461 last 20 years prior to Project commencement.

462
463 **Specific Eligibility Criteria:**

- 464 • In assessing whether land is capable of achieving the height and crown cover criteria
465 specified in the Forest land definition, Project Proponents must consider what the land is
466 capable of achieving in the absence of a change in current (i.e. pre-Project) management
467 practice.
- 468 • Where the Project also involves Improved Forest Management on Project lands where
469 there are also tree planting activities, the Project must be treated as an Improved Forest
470 Management Project according to the requirements of this Protocol and not a tree planting
471 Project. Where a requirement for a tree planting Project is more stringent than for an
472 Improved Forest Management Project (e.g. for determination of relevant versus optional
473 or not relevant SSRs), the more stringent requirement is to be applied.

474
475 **3.2.2 Conservation / Improved Forest Management**

476 **Project Type Definition:**

477 Conservation / Improved Forest Management (CONS/IFM) is defined as a system of practices for
478 stewardship and use of Forest land, which may include production of harvest wood products that
479 reduces GHG Emissions and/or increases GHG Sinks / carbon Reservoirs. CONS projects are
480 not prevented from including a planned harvest cycle.

481
482 Eligible management activities may include one or more of a variety of approaches:

- 483 • Increase sequestration rates (e.g. through fertilization, improving stocking, reducing
484 regeneration delays, use of faster growing trees/seed, etc.),
- 485 • Reduce Emissions (e.g. through capturing mortality, reducing natural disturbances,
486 reducing burning, reducing new road widths, incremental Biomass recovery, etc.), and
- 487 • Increase long-term carbon storage in forests and wood products (e.g. through
488 establishment of conservation areas, reduced harvesting through forest cover constraints,
489 increasing rotation age, increasing proportion of long lived Harvested Wood Products in
490 conjunction with other changes in forest management, etc.).

491

492 **Specific Eligibility Criteria:**

- 493 • Project lands must meet the definition of 'Forest land' for the 20 years immediately prior
494 to the start of the Project.
495

496 **3.2.3 Avoided Conversion**

497 Avoided Conversion (AC) means preventing the direct human-induced conversion of Forest land
498 to a non-Forest land use. Logging as part of forest management is not included as a potential
499 conversion activity under this definition, however AC Projects are not prevented from including a
500 planned harvest.

501
502 Avoided land-uses includes residential, commercial, industrial, agricultural, and Crown land held
503 in fee-simple for municipalities.
504

505 **Specific Eligibility Criteria:**

- 506 • Project lands must meet the definition of 'Forest land' for the 20 years immediately prior
507 to Project commencement, in order to demonstrate that the Project avoids the conversion
508 of Forest land.
- 509 • Project Lands must be suitable for conversion. The evidence and analysis a Proponent
510 should provide in supporting that the Project would be fit for AC must include one or more
511 of the following professional services:
- 512 ○ Highest and Best Use Analysis to determine the reasonably probable use of a
513 property that is legally permissible under current zoning, physically possible,
514 financially feasible, and maximally productive.
 - 515 ○ Feasibility Analysis to determine if a Project will fulfill the objectives of an investor.
 - 516 ○ Market Analysis to determine the supply and demand of a property type and the
517 geographic market area for that property type.
 - 518 ○ Marketability Study to predict how a property will be absorbed under current market
519 conditions.

520 Evidence must be prepared by a Designated Member of the Appraisal Institute of Canada.
521 As per the Canadian Uniform Standards of Professional Appraisal Practice, the appraisal
522 report must have sound judgement and sound reasoning, with sufficient depth and detail,
523 including robust qualitative and quantitative data, to support a sound determination of
524 highest and best use, the impact of any charges and encumbrances on title, prevailing
525 market trends and the final valuation.

- 526 • The Project Proponent must demonstrate that there is an imminent threat of conversion
527 of Project land to a non-Forest land use, according to the Baseline selection requirements
528 in this Protocol. Project Proponents must also include evidence that there is an imminent
529 threat of conversion be included in the Timber Supply Area (TSA), zoning, or appraisal.
530

531 **3.3 PROJECT START DATE**

532 The Project Start Date must be no earlier than January 1, 2017 in accordance with the *Act* and
533 Regulation. Projects accepted under the *Cap and Trade Act* and also accepted by the Director
534 under the *Act* would refer to the original start date of those projects. Project start date must
535 coincide with proof of ownership (see Section 3.1 of this protocol).

536 For Program of Activities (PoA), the Project Start Date is the date of first Project Instance(s).
537

538 **3.4 PROJECT CREDITING PERIOD**

539 The Project Crediting Period is 25 years unless an extension is authorized under the Regulation.
540 The Project Report Period is a minimum of 12 consecutive months and a maximum of five
541 consecutive years.
542

543 **3.5 MATERIALITY THRESHOLD**

544 For the purpose of this Protocol, any errors, omissions, or misrepresentations are considered
545 material if the individual or aggregate effects result in an overestimation or underestimation of the
546 Project Emissions, Emission Reductions, or Removal Enhancements of more than 5% for
547 Projects with net Emission Reductions and Removal Enhancement under 500,000 tonnes of CO₂e
548 (tCO₂e) per calendar year over a Project's Crediting Period, and 2% for Projects with net Emission
549 Reductions and Removal Enhancements over 500,000 tCO₂e per calendar year over a Projects
550 Crediting Period.
551

552 **3.6 DEMONSTRATING ADDITIONALITY**

553 Offset units will only be issued for actions that are considered additional to those that could
554 reasonably be assumed to have happened without the Project.
555

556 Project Proponents must demonstrate that the Primary Activities of the Project will result in
557 Emission Reductions and Removals that exceed:

- 558 • Common practice or “business-as-usual” conditions, and
- 559 • Any law, regulation, permitting conditions or other legally binding mandate associated
560 with the related activity or Project Site to reduce or remove Emissions (with the exception
561 of Regulatory Requirements that were a result of the Project being implemented as
562 determined in Section 6.0).

563
564 The Project Proponent must assert that the Project has not received any financial incentive,
565 including direct funding or a reduction in applicable fees or tax burden reductions on a per unit of
566 reduction/removal basis and that the incentive created by participating in the carbon market was
567 among the main motivating factors for the implementation of the Project.

4.0 PROJECT SITE

4.1 DESCRIPTION OF THE PROJECT

The Project Proponent must provide a description of the Project including where the Project will be carried out and where the Project's Emission Reductions and/or Removal Enhancements will occur.

The Project Plan must indicate whether the Project type is Stand-Alone or PoA.

4.2 IDENTIFICATION OF THE PROJECT AREA

A forest offset Project Proponent must provide geographical information about the location where the Project will be carried out and any other information allowing for the unique identification of the Project. The Project can be contiguous or separated (non-contiguous) tracts.

4.2.1 Stand-Alone Location(s)

Stand-Alone geographic information must include a geo-referenced map that shows the Project area. The Project Proponent is required to use Provincial base mapping, corporate spatial data stored by Data BC. Project area consists of, and must be assessed along the following boundary types:

- Regional Study Area, which is typically based on a natural transition (e.g., watershed boundary, ecological zone) or an artificial delineation (e.g., political or economic district or zone) that is relevant to the Project.
- Local Study Area, which comprises a slightly smaller area, but where the Project Proponent identifies areas that may be influenced by the Project. Within this scale, a Leakage-assessment-area should be included if applicable.
- Footprint, or Project Site, wherein the Project activities will occur.

The map provided must be at a sufficiently large scale, the minimum requirements are: 1:10 000 to 1:50 000, and include sufficient features, place names and administrative boundaries to enable field interpretation and positive identification of the Project area.

The following information must be provided on the map:

- Forest ownership and Project Site (as discussed above).
- Size of forest ownership area.
- Latitude/longitude, or land title or land survey.
- Existing land cover and land use.

The Project Proponent must also provide other Project identification and description information as required by the Regulation.

612 **4.2.2 Program of Activity Locations**

613 Project Plans for a Project involving a PoA must identify the geographic boundary within which
614 the Primary Activity of the Project Scenario will be occurring, and how each Project Instance will
615 be uniquely identified.

616 For all Project Instances implemented at the time of validation, Project Plans must provide Global
617 Positioning System coordinates for the location of each Project Instance and any other relevant
618 information allowing for the unique identification of all Project Instances. Each of the Project
619 Instances must include a geo-referenced map with the same requirements as those Project's that
620 are Stand-Alone location(s)

621 Project Plans of PoAs must describe in detail the approach that will be used for identification of
622 Project Instances that are not determinable when the Project Plan is validated. Project Plans must
623 include a description of how this approach will enable future verifications and inspections to
624 identify each individual Project Instances and ensure the reported Project Instances that have
625 been implemented are uniquely identifiable.

626 As per Section 3.1, Project Proponents must demonstrate right of access for each Project
627 Instance.

628

629

5.0 ESTABLISHMENT OF BASELINE SCENARIO

630

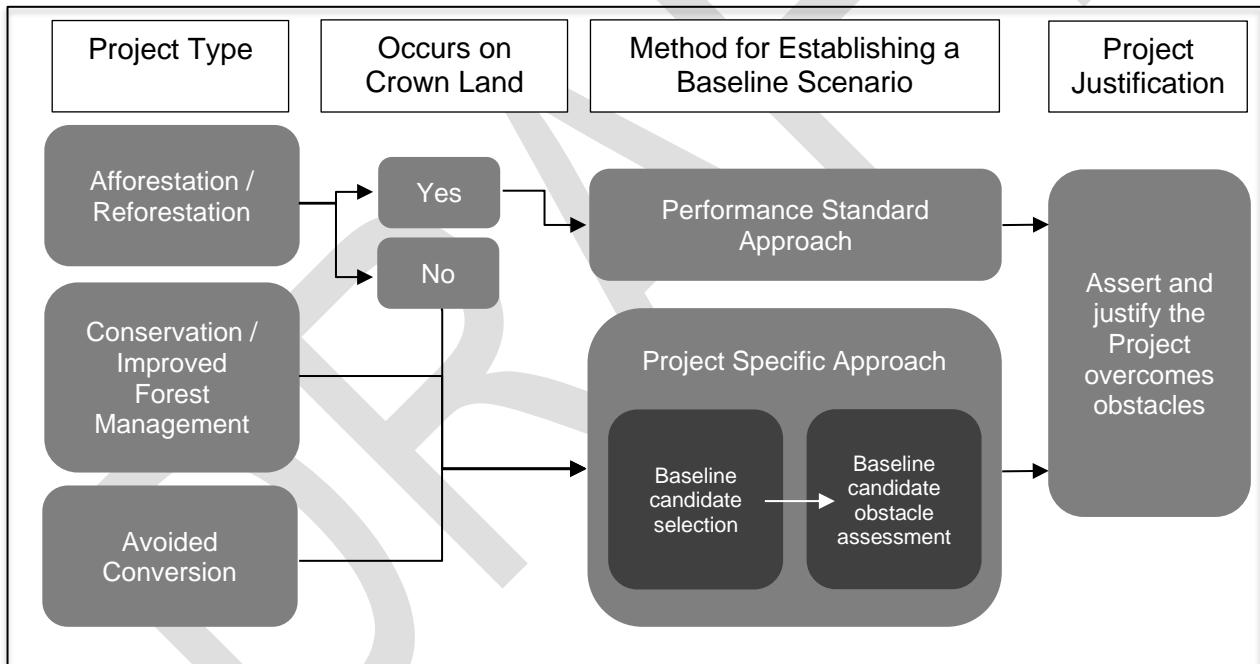

631 To justify the Project, Project Proponents must establish a Baseline Scenario. The Baseline
632 Scenario describes the activities on the Project Site and associated emissions that would have
633 most likely occurred in the absence of the Project. The Baseline Scenario is either determined
634 using a pre-established Performance Standard approach, or a Project Specific approach of
635 Baseline Scenario candidates. For all Baseline Scenario approaches, Project Proponents must
636 determine whether their Project meets specific eligibility criteria described in Section 3.0. Project
637 Proponents must also provide evidence to support the assertion that the Project meets the
638 requirements of each Baseline Scenario approach.

639 Eligibility for the Performance Standard and Project Specific approaches varies by Project type.
640 See Figure 1 below. Following selection of the Baseline Scenario, Project Proponents must assert
641 and justify the Project as per Section 6.0.

642

643

Figure 1: Selection of Baseline Scenario Approaches and Project Justification

644

5.1 PERFORMANCE STANDARD APPROACH

646 For the Performance Standard approach, AFF/REF Project Proponents must determine whether
647 their Project meets specific eligibility criteria described in Section 3.2.1. If Project Proponents
648 meet the eligibility criteria and the Project Site is on Crown land, they must use the Performance
649 Standard Baseline Scenario established in this section to estimate their Baseline Emissions.

650

651

652

5.1.1 Identifying a Performance Standard Baseline

653 AFF and REF Projects on Crown land must use the Performance Standard Approach. AFF and
654 REF Projects on non-Crown land, including private, municipal, reserve land, Aboriginal title land,
655 or other non-Crown land, must use the Project Specific Approach under Section 5.2.

656

657 Eligible Project Proponents must select one of the following three types of Performance Standard
658 Baseline Scenarios that may apply depending on attributes specific to the Project:

659

- 660 1) A Regulatory Requirements Baseline Scenario, or
- 661 2) A continuation of historic activities Baseline Scenario, or
- 662 3) A hybrid of continuation of historic activities and Regulatory Requirements Baseline
663 Scenario.

664

665 The Project Plan must demonstrate which form of Performance Standard Baseline Scenario is
666 applicable for the Project. The following conditions determine whether a Project Proponent uses
667 a Regulatory Requirement Performance Standard Baseline Scenario or a continuation of historic
668 activities Performance Standard Baseline Scenario. The Project Plan must identify and supply
669 sufficient evidence to demonstrate which criterion has been met and provide an assertion that the
670 selected criterion has been met.

671

672 Performance Standard Baseline Scenario Conditions

673

- 674 1. Projects without any Regulatory Requirement must use a continuation of historic
675 practices/activities as the Baseline Scenario.
- 676 2. Projects that face Regulatory Requirements that were not a result of the Project being
677 implemented as determined in Section 6.0 must use those Regulatory Requirements as
678 the Baseline Scenario. Project Proponents must also take into account provincial or
679 federal incentives or Regulatory Requirements relevant to any aspect of the Baseline
680 Scenario, including tax incentives and grants.

681

682

5.1.2 Selecting a Performance Standard Baseline Scenario

683 The Baseline Scenario for a Performance Standard approach is the threshold or activity described
684 in Section 3.2.1. The Project Proponent must assert in the Project Plan that the Baseline Scenario
685 will result in the most conservative estimate of the Project Reductions.

686

687

5.2 PROJECT SPECIFIC APPROACH

688 AFF/REF Projects on private land eligible under Section 3.2.1, CONS/IFM Projects eligible under
689 Section 3.2.2, and AC Projects eligible under Section 3.2.3 must use the Project-Specific
690 approach for determining the Baseline Scenario. Under this Baseline Scenario approach, Project
691 Proponents must identify and select a Baseline Scenario representing what would have most
692 likely occurred in the absence of the Project. The Baseline Scenario must ensure a conservative
693 estimate of the Project Reductions. The Project Proponent must first identify plausible Baseline
694 Scenario candidates assuming the Project had not taken place and then systematically assess

695 the validity of each, considering any obstacles and Regulatory Requirements facing each
696 Baseline Scenario candidates.

697

698 **5.2.1 Identification of Baseline Scenario Candidates**

699 The Project Specific Baseline Scenario approach must identify all Baseline Scenario candidates.
700 Baseline Scenario candidates for AFF/REF projects must be selected from Section 5.2.1.1,
701 Baseline Scenario candidates for CONS/IFM Projects must be selected from Section 5.2.1.2, and
702 Baseline Scenario candidates for AC Projects must be selected from Section 5.2.1.3.

703

704 The assessment must consider each type of candidate (hypothetical natural resource
705 management practice or activity) individually, and include a clear description of what each activity
706 involves (associated activities, schedules, etc.). Candidates must use a time-horizon identical to
707 that of the proposed Project.

708

709 All Project Proponents must include the following candidates:

710

- 710 • Initiating the project without carbon financing,
- 711 • Continuation of historic practices (unless there has been a acquisition of the Project Site
712 in the past 20 years, in which case this candidate is optional), and
- 713 • New regulatory requirements.

714

715 **Continuation of historic practices baseline candidate requirements**

716 To determine the historic natural resource management activities in place prior to commencement
717 of the Project, the Project Proponent must prepare a verifiable record of historic natural resource
718 management (including timber harvesting) practices occurring on the Project Site prior to the
719 Project, for a period of at least 20 years. The Project Proponent must also assess (with
720 documentation) whether or not in the absence of the project, the land would continue to be
721 managed according to historic forest management practices by considering at minimum:

722

- 722 • Existing or proposed regulatory requirements,
- 723 • Provincial or Federal incentives,
- 724 • Financial implications of historic forest management practices, and
- 725 • Common forest management practices within a geographic region that includes the
726 Project, with the size of the region and time period considered to be justified by the
727 proponent.

728

729 **5.2.1.1 Baseline Scenario Candidates for Afforestation/Reforestation Projects**

730 AFF/REF projects may use all the following Baseline Scenario Candidates:

731

- 731 • Project without carbon financing
- 732 • Production of commercial crops
- 733 • Pastureland, abandoned land, or degraded land
- 734 • Land development (i.e. residential, commercial, or industrial)
- 735 • Continuation of historic practices and regulatory requirements
- 736 • New regulatory requirements that do not justify the project as determined in Section 6.0
737 Project Justification

738

739 5.2.1.2 Baseline Scenario Candidates for Conservation/Improved Forest Management
740 Projects

741 CONS/IFM projects may use all of the following Baseline Scenario Candidates:

- 742 • Project without carbon financing
- 743 • Park or protected area status
- 744 • Harvest to projected Annual Allowable Cut (AAC) (Crown land)
- 745 • Harvest at historical harvest rates, or continuation of historic practices and regulatory
- 746 requirements
- 747 • New regulatory requirements that do not justify the project as determined in Section 6.0
- 748 Project Justification.
- 749 • Harvest to long-term sustainable yield

750

751 5.2.1.3 Baseline Scenario Candidates for Avoided Conversion Projects

752 AC project may use all of the following Baseline Scenario Candidates:

- 753 • Project without carbon financing
- 754 • Park or protected area status
- 755 • Harvest at historical harvest rates, or continuation of existing management and regulatory
- 756 requirements
- 757 • New regulatory requirements that do not justify the project as determined in Section 6.0
- 758 Project Justification.
- 759 • Scenarios that reflect the nature of land development activities in the region
- 760 • Proposed (but not yet in effect) natural resource management activities for the Project
- 761 lands (which defines the type of land use that the Project would intend to avoid by initiating
- 762 the Project)

763

764 A Project Proponent must provide the following documentary and explanatory evidence for each
765 of the Baseline Scenario candidate:

766

- 767 • An assessment of development practices, including development density, typical
- 768 development area to meet the stated need, typical extent of deforestation, and timing of
- 769 development. For land uses selected as equivalent to the selected Baseline Scenario
- 770 candidate, the size of the region and time period must be justified by the Project
- 771 Proponent.
- 772 • If the Baseline Scenario candidate does not reflect identified common development
- 773 practices, then the Project Proponent must provide an explanation of why the Baseline
- 774 Scenario candidate would be different for the Project Site, including the identification and
- 775 explanation of key criteria used to make the assessment.
- 776 • Where the Baseline Scenario candidate does not involve developing the Project Site in a
- 777 way that satisfies non-Forest land demand in the Baseline Scenario, for example, where
- 778 the Project involves managing the Project Site as a forest with no development, or where
- 779 Project development differs from Baseline Scenario candidate development:
 - 780 ○ An approved development plan / permit for the Project Site issued within two years
 - 781 of Project Start Date indicating that the Baseline Scenario candidate development
 - 782 has been approved, or
 - 783 ○ A written offer to purchase the Project Site issued within the two years prior to
 - 784 Project start, by a developer that is completely independent of the Project
 - 785 Proponent, and where it can be convincingly demonstrated that the developer
 - 786 would have undertaken the development and deforestation of the Project lands

787 according to the selected Baseline Scenario candidate (including how any
788 identified obstacles to the Baseline Scenario would be overcome), or
789 ○ An economic analysis of the selected Baseline Scenario candidate demonstrating
790 the Baseline Scenario candidate is financially viable and more attractive than
791 maintaining the Project lands as Forest land without development and more
792 financially attractive than the Project.
793

794 Projects that involve developing the Project Site in a way that satisfies non-Forest land demand
795 in the Baseline Scenario must consider the financial viability of the Project as part of the Project
796 justification assessment described in Section 6.0.
797

798 **5.2.2 Identification of Baseline Scenario Candidate Obstacles**

799 The Project Plan must identify any potential obstacles associated with each of the Baseline
800 Scenario candidates identified as per Section 5.2.1, in order to assess, as per Section 5.2.3, which
801 of the Baseline Scenario candidates would have been the most likely to occur in the absence of
802 the Project, considering both the number and magnitude of the obstacles.
803

804 **5.2.2.1 Baseline Scenario Candidate Obstacle Types**

805 Project Proponents must identify obstacles that would discourage a decision to implement the
806 Baseline Scenario candidates. Project Proponents must consider, at minimum, financial, legal
807 and technical obstacles that each identified Baseline Scenario candidate may face.
808

809 Examples of Baseline Scenario candidate obstacles include:

- 810 • The Baseline Scenario candidate is less financially attractive than the Project Proponent's
811 established and documented internal investment hurdle rate even taking into account
812 existing government climate change or other incentives,
- 813 • The Baseline Scenario candidate faces restrictions on access to capital (e.g. due to high
814 up-front capital costs),
- 815 • The Baseline Scenario candidate faces certain supply chain challenges (e.g. cost
816 effectively getting their product to market cost or delivering an important input to the
817 Project site),
- 818 • The Baseline Scenario candidate involves technologies / approaches with which the
819 Project Proponent is not experienced (e.g. not a core business of the Project Proponent).
820 Thus, even if profitable, the Project Proponent would not normally have undertaken the
821 Baseline Scenario candidate, and
- 822 • The Baseline Scenario candidate faces legal obstacles that prevent it from being
823 undertaken.
824

825 **5.2.2.1.1 Avoided Conversion Baseline Scenario Candidate Obstacles**

826 The Project Proponent must include in the assessment of each Baseline Scenario candidate
827 obstacles, at minimum, when evaluating each Baseline Scenario candidate for AC Projects:

- 828 • Legal, including consideration of zoning by-laws, development permits, tree protection by-
829 laws, riparian regulations, covenants, easements, existing right of ways and any other
830 relevant Project land-specific, local or other legal requirements,
- 831 • Official community development plans,
- 832 • Official regional growth strategies, and

- 833 • Strategic land-use plans and higher-order plans (e.g. as emerge from land and resource
834 management planning processes).
835

836 **5.2.3 Comparative Assessment of Baseline Obstacles**

837 Project Proponents must present a comparative assessment of obstacles for each of the Baseline
838 Scenario candidates. Project Proponents must identify both the presence of an obstacle and
839 estimate the magnitude of the obstacle for each Baseline Scenario candidate identified as per
840 Section 5.2.2. The magnitude of an obstacle must be quantified as much as practicable. In
841 addition, the magnitude of an obstacle may also be characterized qualitatively using descriptive
842 explanations and justifications for the characterization. In the Project Plan, Project Proponents
843 must substantiate and explain the cumulative effects of the obstacles for each Baseline Scenario
844 candidate. The results of cumulative effects must be presented so that a reasonable person could
845 form an opinion as to which of the Baseline Scenario candidates is most likely to occur.

846 For clarity, as part of this selection, in accordance with Section 14(3)(n)(v)(A) of the Regulation,
847 Project Proponents must take into account provincial or federal incentives or Regulatory
848 Requirements relevant to any aspect of the Baseline Scenario, including tax incentives and
849 grants. In accordance with Section 14(3)(n)(v)(B) of the Regulation, in the Project Plan, the Project
850 Proponent must also include in the assessment the financial implications of carrying out a course
851 of action referred to in the Baseline Scenario, and any other factor relevant to justifying the
852 assertion that the estimate of future Project Reductions will be conservative in accordance with
853 Section 14(3)(n)(v)(C).
854

855 **5.2.4 Selecting a Project Specific Baseline Scenario**

856 Based on the results of the comparative assessment of Baseline Scenario obstacles, a Project
857 Proponent must determine and justify which of the Baseline Scenario candidates is the most
858 reasonably likely to occur. Where there is only one Baseline Scenario candidate that is reasonably
859 likely to occur, the Project Plan establishes that Baseline Scenario candidate as the Baseline
860 Scenario. Where there are multiple Baseline Scenario candidates that are reasonably likely to
861 occur, the Project Plan establishes a Baseline Scenario that will result in the most conservative
862 estimate of the Project Reduction supported with adequate and appropriate justification for the
863 selection. The Project Proponent must assert in the Project Plan that that the Baseline Scenario
864 will result in the most conservative estimate of the Project Reductions.
865

866 **5.3 ADJUSTMENTS TO THE BASELINE SCENARIO**

867 The Baseline Scenario may be adjusted if there are substantive changes to applicable inputs,
868 candidates, or candidate obstacles.

869

870

871

6.0 PROJECT SCENARIO JUSTIFICATION

872

873 Project Proponents must assert and justify in the Project Plan that there are financial,
874 technological, or other obstacles to carrying out the Project that are overcome or partially
875 overcome by the incentive of having the Project Reductions recognized as Offset Units under the
876 *Act*. Project scenario obstacle identification uses the same process as Section 5.2.2. The
877 justification in the Project Plan must include:

- 878 • Financial analysis including the impact of carbon finance on investment hurdle rates and
879 decision-making, and
- 880 • How the economic business case and values used in the financial analysis compare to
881 those commonly used by the Project Proponent and industry-specific standards.

882

883 The situation where a Project creates Emission Reductions and/or Removal Enhancements
884 partially or wholly through an agreement with government to change legislation or regulation for
885 the purposes of increasing carbon sequestration and thereby creating incremental Project
886 Reductions may constitute evidence of overcoming or partially overcoming obstacles.

887

888 Project Proponent must assert that the Emissions Reduction projected in the Project Plan have
889 not been or will not be applied in relation to a regulatory requirement under another enactment
890 and therefore, are in excess of those GHG Emission regulatory requirements. Project Proponents
891 must also clearly identify any regulatory requirements that may come into force.

892

893

896
897
898
899
900
901
902
903

All Sinks, Sources and Reservoirs (SSRs) are categorized as controlled, related, or affected (C / R / A) based on their relation to the Project Proponent, where the Project Proponent is assumed to control all on-site and mobile SSRs and upstream and downstream SSRs are assumed to be controlled by others and, thus, are related to the Project. If applicable, affected SSRs are determined separately in Section 8.08.3. Figure 2 shows the various SSRs and their relation to the Project.

931

932 7.1 CATEGORIZATION OF PROJECT AND BASELINE SSRs

933 Subject to any limitations in the description column of Table 1, the Project Plan must include all
934 SSRs identified in Table 1 that are applicable to their Project type as ‘included’, and may include
935 SSR identified as “Project Proponent Justification” as applicable by the Project Proponent. The
936 Project Plan must not include any SSRs that are not listed in Table 1. Potential SSRs that would

937 be subject to carbon pricing are omitted from this protocol. Where the Project Plan lists an SSR,
938 Emissions or Removals of all GHGs listed for that SSR are to be included. In Table 1, the letter
939 in column 1 under heading SSR denotes whether the SSR is Project (P) or Baseline (B) and the
940 number denotes the SSR reference value.

941
942
943

DRAFT

7.2 SELECTED RELEVANT PROJECT AND BASELINE SSRs

945 **Table 1: Selected Relevant Project and Baseline SSRs**

SSR	Controlled, Related or Affected		GHG	Included/Excluded			Description
	Baseline	Project		AFF/REF	C/IFM	AC	
Removal Sinks and Reservoirs							
PR1/BR1 Standing Live Trees	Controlled	Controlled	CO ₂	Included	Included	Included	Standing live trees include the stem, branches, and leaves or needles of all above ground live Biomass, regardless of species. A minimum diameter at breast height threshold may be justified by the Project Proponent based on the requirements of models and field sampling techniques used.
PR2/BR2 Shrubs and Herbaceous Understory	Controlled	Controlled	CO ₂	Included	Optional.	Optional	All above-ground live woody and other plant Biomass that does not meet the description of Standing Live Trees. Note on Optional for CONS/IFM Projects and AC Projects: Project Proponent may elect to consider this SSR to be relevant, but this carbon Reservoir is typically very small in established forests and IFM Projects.
PR3/BR3 Live Roots	Controlled	Controlled	CO ₂	Included	Included	Included	Portions of living trees, shrubs or herbaceous Biomass located below ground, principally roots.
PR4/BR4 Standing Dead Trees	Controlled	Controlled	CO ₂	Included	Included	Included	Standing dead trees include the stem, branches, roots, or section thereof, regardless of species. Stumps are not considered standing dead stocks. A minimum diameter at breast height threshold may be justified by the Project Proponent based on the requirements of models and field sampling techniques used.
PR5/BR5 Lying Dead Wood	Controlled	Controlled	CO ₂	Project Proponent Justification	Project Proponent Justification	Project Proponent Justification	Any piece(s) of dead woody material from a tree (e.g. dead boles, limbs, and large root masses) on the ground in forest stands. Lying dead wood is all dead tree material with a minimum average diameter of 12.5cm and a minimum length of 2.4m. Anything not meeting the measurement criteria for lying dead wood will be considered litter. Stumps are not considered lying dead wood. Note on Project Proponent Justification: Project Proponent may elect to consider this SSR to be relevant, but explanation is not required to deem this SSR as not relevant, since AFF

SSR	Controlled, Related or Affected		GHG	Included/Excluded			Description
	Baseline	Project		AFF/REF	C/IFM	AC	
							<p>projects would increase carbon stored in the lying dead wood carbon Reservoir relative to the Baseline.</p> <p>Note on Included for REF Projects and IFM Projects: This SSR is included if it cannot be demonstrated that the Project will involve the same amount or more carbon being stored in the lying dead wood carbon Reservoir than the Baseline.</p>
PR6/BR6 Litter & Forest Floor	Controlled	Controlled	CO ₂	Project Proponent Justification	Project Proponent Justification	Project Proponent Justification	<p>Any piece(s) of dead woody material from a tree (e.g. dead boles, limbs, and large root masses) on the ground in forest stands that is smaller than material identified as lying dead wood.</p> <p>Note for AFF Projects and AC Projects: Project Proponent may elect to consider this SSR to be relevant, but explanation is not required to deem this SSR as not relevant, since AFF Projects would increase carbon stored in the Litter carbon Reservoir relative to the Baseline.</p> <p>Note for REF Projects and IFM Projects: Unless it is demonstrated that the Project will involve the same or more carbon being stored in the Litter carbon Reservoir than the Baseline, this SSR <u>may be</u> conservatively deemed not relevant.</p>
PP7/BR7 Soil	Controlled	Controlled	CO ₂	Conditional	Conditional	Conditional	<p>Belowground carbon not included in other Reservoirs including Stand-Alone. Soil pits are ≥ 60 cm deep, unless bedrock or a water table is encountered before reaching this depth (depth starting at surface of the mineral soil). In deep organic soils, the soil pit should be excavated to a minimum depth of 100 cm when possible. Can be a net Sink or Emission Source depending on the circumstances.</p> <p>Note on Included: SSR is included if the Project exceeds the soil disturbance limits as set out in Section 35 (3), Part 4, Practice Requirements, Division 1 — Soils of the <i>Forest and Range Practices Act, Forest Planning and Practices Regulation</i>, regardless of whether or not the Regulation would otherwise apply to the Project Site. Also relevant where the Project involves lowering the water table relative to the Baseline case through physical alteration of the Project Site (e.g. trenching).</p>

SSR	Controlled, Related or Affected		GHG	Included/Excluded			Description
	Baseline	Project		AFF/REF	C/IFM	AC	
PR8/BR8 Harvested Wood Products in Use	Related	Related	CO ₂ CH ₄	Included	Included	Included	Wood that is harvested or otherwise collected from the forest, transported outside the forest Project Site, and being processed or in use. Includes raw wood products, finished wood products, and any wood residuals generated during the HWP lifecycle that is still in use (i.e. has not been burned, disposed of, etc.).
Emission Sources							
PE1/BE1 Fertilizer Production	Related	Related	CO ₂ CH ₄ N ₂ O	Included if PE > BE. If not, then Excluded	Included if PE > BE. If not, then Excluded	Included if PE > BE. If not, then Excluded	Raw material extraction through to final production of fertilizers that are used throughout the Project.
PE2/BE2 Fertilizer Use Emissions	Controlled	Controlled	N ₂ O	Included if PE > BE. If not, then Excluded	Included if PE > BE. If not, then Excluded	Included if PE > BE. If not, then Excluded	Application of nitrogen-based fertilizers and associated Emission pathways, including Emission from soil, volatilization, leaching and runoff.
PE3/BE3 Biomass Combustion	Controlled	Controlled	CO ₂ CH ₄ N ₂ O	Included if PE > BE. If not, then Excluded	Included if PE > BE. If not, then Excluded	Included if PE > BE. If not, then Excluded	Emissions from the combustion of harvested forest Biomass at the Project Site, or downstream of the Project Site for various purposes, including for heating, slash pile burning, or HWP processing.
Leakage							
L1/L2 Forest Carbon and Wood Product Reservoirs Located Outside of the Project Physical Boundary that are Indirectly Affected by the Project Activity	Affected	Affected	CO ₂ CH ₄ N ₂ O	Conditional – see Note for Included and Excluded	Conditional – see Note for Included and Excluded	Conditional – see Note for Included and Excluded	Changes in the amount of carbon stored in forest and/or wood product carbon Reservoirs located outside of the Project Site indirectly caused by the Project. See Section 7.2.1 for more information.

946

947 **7.2.1 Notes on the Categorization and Description of Leakage (L1/L2)**

948 Project activities that result in the change in the level of a service provided from within the Project
949 Site (e.g. amount of wood harvested or wood products produced) may result in changes in the
950 level of services provided outside the Project Site, including areas within as well as outside B.C.,
951 due to market forces or shifting of forestry activities to another location.

952
953 Such changes, which are often referred to as ‘Leakage,’ may result in changes in the amount of
954 carbon stored in forest and/or wood product carbon Reservoirs located outside of the Project Site.
955 These changes caused by the Primary Activity, might serve to cancel out or mitigate Emission
956 Reductions or enhanced sequestration achieved by the Project within the Project Site. A
957 description and further determination of Leakage is included in Section 8.3.1 and Section 8.3.2.
958

959 **7.2.1.1 Land Use-shifting Leakage**

960 Note on Included: SSR is included in the following situations, as long as Project Emissions from
961 affected Reservoirs are positive:

- 962 • AFF/REF Projects, where shifting to other lands owned or controlled by the Project Proponent
963 (“internal Leakage”).

964 Note on Excluded: SSR is excluded if Project Emissions from affected Reservoirs is zero or
965 negative, or in the following situations:

- 966 • AFF/REF Projects, where shifting is to lands outside the ownership or control of the Project
967 Proponent. This type of Leakage is not expected to occur for Projects in B.C. since it is not
968 anticipated that an AFF/REF Project would occur on land that was being actively and profitably
969 being used for other activities (e.g. farming, grazing, industrial use, etc.), given the economics
970 and financial obstacles associated with AFF/REF Projects.
- 971 • CONS/IFM Projects must not cause land use change.

972

973 **7.2.1.2 Harvest-shifting Leakage**

974 Note on Included: SSR is included as long as Project Emissions from affected Reservoirs are
975 positive where the Project results in a decrease in HWP production relative to the Baseline.

976 Note on Excluded: SSR is excluded if Project Emissions from affected Reservoirs is zero or
977 negative, or where the Project results in no change or an increase in HWP production relative to
978 the Baseline, including Projects where there was no harvesting in the Baseline.

979

980 **7.3 EXCLUSIONS**

981

982 Project Proponents may exclude Sources from calculation if it can be demonstrated that Project
983 Emissions will be sufficiently less than Baseline Emissions. Project Proponents may only exclude
984 Reservoirs if indicated in Table 1.

985 **8.0 QUANTIFICATION OF EMISSION REDUCTIONS AND**
 986 **REMOVAL ENHANCEMENTS**

987
 988 For each selected SSR identified in Table 1, a calculation method is provided for quantifying
 989 associated GHG Emissions in the Project and Baseline Scenarios in the following sections. All
 990 SSRs must be reported in tonnes of carbon dioxide equivalent.

991
 992 Net Project Emission Reductions and Removal Enhancements are determined through Equation
 993 1.

994
 995
 996 **Equation 1: Net Project Emission Reductions and Removal Enhancements in CO₂e**

997 $\Delta CO_{2e_{net}} = \Delta GHG_{net} - L1 - L2 - CON_{\beta} - Other\ deductions$

998
 999 Where,

Parameter	Description	Default Value
$\Delta CO_{2e_{net}}$	Net Emission Reductions and Removal Enhancements of CO ₂ e, in tonnes, achieved by the Project Proponent during reporting period as compared to the Baseline (tCO ₂ e). A net increase in Emission Reductions and Removal Enhancements is expressed as a positive number.	N/A
ΔGHG_{net}	Net incremental Emission Reductions and Removal Enhancements of CO ₂ e before deductions, achieved by the Project during the Project Report Period as compared to the Baseline (tCO ₂ e). A net increase in Emission Reductions and Removal Enhancements is expressed as a positive number. Determined using Equation 2.	N/A
$L1$	Net increase in Project Emissions due to Land Use-shifting Leakage from all affected carbon Reservoirs during each Project Report Period (tCO ₂ e). Determined using Equation 20.	N/A
$L2$	Net increase in Project Emissions due to Harvest-shifting Leakage from all affected carbon Reservoirs during each Project Report Period (tCO ₂ e). Determined in Section 0.	N/A
CON_{β}	Contributions to the Contingency Account during each Project Report Period. Expressed as tCO ₂ e. Determined using Equation 28.	N/A
<i>Other deductions</i>	Other deductions established in an Atmospheric Benefits Agreement, Indigenous Atmospheric Benefit Agreement, Atmospheric Benefits Sharing Agreement, or other contractual obligations (if relevant) (tCO ₂ e).	N/A

1000
 1001 Emissions factors can be found in the National Inventory Report (NIR) unless stated otherwise. A
 1002 summary table of current emission factors and constants can be found in Appendix A.
 1003

1004

1005 **Equation 2: Net Project Emission Reductions and Removal Enhancements Before**
 1006 **Deductions**

1007 $\Delta GHG_{net} = \Delta GHG_{Project,t} - \Delta GHG_{Baseline,t}$

1008
 1009 Where,

Parameter	Description	Default Value
ΔGHG_{net}	Net incremental Emission Reductions and Removal Enhancements of CO ₂ e before deductions, achieved by the Project during the Project Report Period as compared to the Baseline (tCO ₂ e). A net increase in Emission Reductions and Removal Enhancements is expressed as a positive number.	N/A
$\Delta GHG_{Project,t}$	Total Emissions or Removals of CO ₂ e occurring in the Project during the Project Report Period <i>t</i> (tCO ₂ e). Determined using Equation 3.	N/A
$\Delta GHG_{Baseline,t}$	Total Emissions or Removals of CO ₂ e occurring in the Baseline during the Project Report Period <i>t</i> (tCO ₂ e). Determined using Equation 19.	N/A

1010
 1011 Retroactive adjustments to Baseline or Project Emission Reductions or Removal Enhancements
 1012 from previous Project Reporting Periods is encouraged, but will not be considered as justification
 1013 for retroactive crediting by the Regulator in the event adjustments to estimates or modelling occur
 1014 resulting in additional Emission Reductions or Removal Enhancements for retroactive Project
 1015 Report Periods. If it is determined that the use of modelled results led to over-crediting of the
 1016 Project, then the Project Proponent must indicate such on the current Project Report, and must
 1017 deduct credits from net Emission Reductions and Removal Enhancements of that current Project
 1018 Report Period (and subsequent Project Report Periods if applicable).

1019 **8.1 QUANTIFICATION OF PROJECT EMISSIONS AND REMOVALS**

1020 Project Emission Reductions and Removal Enhancements are determined with Equation 3.

1021
 1022
 1023
 1024
 1025
 1026
 1027
 1028
 1029
 1030

1031 **Equation 3: Total Project Emission Reductions or Removal Enhancements**

1032 $\Delta GHG_{Project,t} = \Delta T_{(PR1\ to\ PR7)} + T_{PR8} - T_{PE1} - T_{PE2} - T_{PE3} - T_{PE4} - T_{PE5}$

1033
1034 Where,

Parameter	Description	Default Value
$\Delta GHG_{Project,t}$	Total Emissions or Removals of CO ₂ e occurring in the Project during the Project Report Period <i>t</i> (tCO ₂ e).	N/A
$\Delta T_{(PR1\ to\ PR7)}$	Emissions and Removals by Project live and dead forest carbon Reservoir (excluding HWPs) during each Project Report Period (tCO ₂ e). Determined using Equation 4.	N/A
T_{PR8}	Mass of CO ₂ stored in Project HWPs during each Project Report Period (tCO ₂ e). Determined using Equation 7.	N/A
T_{PE1}	Emissions from PE1 from fertilizer production that will be applied during each Project Report Period (tCO ₂ e). Determined using Equation 10.	N/A
T_{PE2}	Emissions from PE2 from nitrogen application within the Project Site during each Project Report Period (tCO ₂ e). Determined using Equation 11.	N/A
T_{PE3}	Emissions from PE3 from Biomass combustion within the Project Site and downstream during each Project Report Period (tCO ₂ e). Determined using Equation 18.	N/A

1035
1036

1037 **8.1.1 PR1 to PR7 Live and Dead Forest Carbon Reservoirs**

1038 Project Reservoirs (PR) PR1 to PR7 associated with Project forest growth must be determined
1039 using **Error! Reference source not found.**, Equation 5, and Equation 6 below.

1040

1041 **Equation 4: Converting Carbon to Carbon Dioxide Units**

1042 $\Delta T_{(PR1\ to\ PR7)} = \sum \Delta T_{PCR} \times \frac{MW_{CO2}}{MW_C}$

1043 Where,

Parameter	Description	Default Value
$\Delta T_{(PR1\ to\ PR7)}$	Emissions and Removals by Project live and dead forest carbon Reservoir (excluding HWPs) during each Project Report Period (tCO ₂ e).	N/A
ΔT_{PCRi}	Change in total Project carbon Reservoir in mass for SSR <i>i</i> during each Project Report Period (tC). Determined using Equation 5.	N/A
MW_{CO2}	Molecular weight of CO ₂ .	44 g/mole
MW_C	Molecular weight of carbon.	12 g/mole

1044

1045

1046 **Equation 5: Summation of Change in Carbon Reservoirs**

1047 $\Delta T_{PCR_i} = \Delta PCR1 + \Delta PCR2 + \Delta PCR3 + \Delta PCR4 + \Delta PCR5 + \Delta PCR6 + \Delta PCR7$

1048

1049 Where,

Parameter	Description	Default Value
$\Delta T_{PCR,i}$	Change in total Project carbon Reservoir in mass for SSR <i>i</i> (tC) during the Project Report Period.	N/A
$\Delta PCR1$	Change in carbon by Project Reservoir standing live trees during the Project Report Period (tC).	N/A
$\Delta PCR2$	Change in carbon by Project Reservoir shrubs and herbaceous understory during the Project Report Period (tC).	N/A
$\Delta PCR3$	Change in carbon by Project Reservoir live roots during the Project Report Period (tC).	N/A
$\Delta PCR4$	Change in carbon by Project Reservoir standing dead trees during the Project Report Period (tC).	N/A
$\Delta PCR5$	Change in carbon by Project Reservoir lying dead wood during the Project Report Period (tC).	N/A
$\Delta PCR6$	Change in carbon by Project Reservoir litter & forest floor during the Project Report Period (tC).	N/A
$\Delta PCR7$	Change in carbon by Project Reservoir soil during the Project Report Period (tC).	N/A

1050

1051

1052 **Equation 6: Reporting Change of Carbon in Reservoirs**

1053 $\Delta T_{PCR,i} = PCR_{i,t} - PCR_{i,t-1}$

1054

1055 Where,

Parameter	Description	Default Value
$\Delta T_{PCR,i}$	Change in total Project carbon Reservoir in mass for SSR <i>i</i> (tC) during the Project Report Period.	N/A
$T_{PCR,i,t}$	Project carbon Reservoir for SSR <i>i</i> in Project Report Period <i>t</i> .	N/A
$T_{PCR,i,t-1}$	Project carbon Reservoir for SSR <i>i</i> in Project Report Period <i>t</i> - 1.	N/A

1056

1057 The Reservoirs are identified by a Project Proponent in the Project Plan as selected based on the
 1058 requirements in Section 6.07.2. Project Proponents must demonstrate in the Project Plan that the
 1059 components of forest carbon included in the definitions of each selected Reservoir were assessed
 1060 as part of the quantification approach used.
 1061

Guidance Note: PR7 Soil

Where soil carbon is selected as a carbon Reservoir by the Project Proponent, the Project Proponent must ensure that either:

- The forest carbon model employed have the capability to quantify changes in soil carbon between the Project and Baseline over time, or
- Direct field sampling for assessing soil carbon is selected and paired with the selected forest carbon models.

A Project Proponent must justify their selection of a soil carbon quantification method, taking into account Project-specific details including the Baseline Scenario. The Project Proponent must indicate in the Project Plan how their approach will result in a conservative estimate of Project Reductions, considering the associated uncertainty. The frequency of field measurement must be consistent with the requirements for assessing other forest carbon Reservoirs as described later in the Protocol (i.e. at least every 10 years). Soil carbon assessment must include a full site-specific soil profile.

Where uncertainty cannot be effectively managed (as defined in the field sampling method), and where soil carbon is an optional Reservoir in Table 1, this carbon Reservoir may not be selected for quantification.

1062
1063

1064 **8.1.1.1 Quantification Approach and Associated Uncertainty**

1065
1066
1067

There are two options for quantification of carbon Reservoirs in the Project Scenario:

- 1068 a) Periodic direct field sampling measurement coupled with conversion factors / equations to
1069 convert the measured forest attributes (i.e. diameter at breast height and height) into amount
1070 of stored Biomass/carbon, or
1071 b) Modelling / Inventory approach using current forest inventory information coupled with growth
1072 and yield models to project future forest status.

1073 **8.1.1.1.1 Field Sampling Method (Direct Measurement)**

1074

1075 The Project Proponent must use Vegetative Resource Index (VRI) or National Forest Inventory
1076 (NFI) standards for conducting field sampling and forest inventories, and this sampling must be
1077 supervised by a qualified RPF. Sample plots must be chosen using a justified statistically valid
1078 approach appropriate for the Project (e.g. that reflects any site stratification, etc.).

1079 Project Proponents that select the field sampling method must demonstrate in the Project Plan
1080 that the following requirements have been met:

- 1081 • Field sampling must be conducted at minimum once every 10 years, including at the start
1082 of the Project and at the end of the Project. A Project Proponent is permitted to report on
1083 and claim Offset Units from Emission Reductions and Removal Enhancements in years
1084 where sampling was not conducted (e.g. annual reporting is still permitted based on the
1085 average between the two periods).
1086 ○ Verification Bodies must conduct a site audit as part of each verification.
- 1087 • Results of the sampling must be converted into amounts of stored carbon in relevant forest
1088 carbon Reservoirs based on justified assumptions. The targeted sampling error for total
1089 Biomass/carbon should be less than or equal to 20% at 90% confidence level for both
1090 plantation and natural forests. In converting sampling results to amount of forest carbon,
1091 the principle of conservativeness must apply.

- 1092
- 1093
- 1094
- 1095
- Where a Project includes multiple Project Instances, Project Instances must be homogenous, otherwise non-homogenous Project Instances must be measured separately.

1096 *8.1.1.1.2 Inventory / Modeling Method (Indirect Measurement)*

1097

1098 While rigorous re-measurement of field conditions typically provides more precision than modeled
1099 projections, for large and diverse forest estates (or in some cases small but remote Projects)
1100 intensive sampling may be prohibitively expensive. For diverse tracts, modelling forest carbon
1101 changes for each stand, or for stratified groupings of similar stands, over time with amalgamation
1102 of results across the Project landbase may provide sufficiently accurate estimates without
1103 intensive field sampling. This approach would focus on tracking and verification of the timing and
1104 extent of any Project activities, along with some minimum level of field measurement at the Project
1105 Site, though the type and level of measurement would be determined by the Project Proponent
1106 (see below for further details).

1107

1108 Vegetation Resource Inventory standards (VRI) must be used to develop a new forest inventory
1109 if the VRI is not available for the Project. At each Project Reporting Period, Project Proponents
1110 must update projections for any disturbances that have occurred on the landbase (e.g. harvesting,
1111 etc.) and based on the results of any valid field sampling that is conducted. For Crown land, the
1112 accuracy assessments and quality assurance associated with VRI datasets are currently available
1113 and updated on an ongoing basis. The Project Proponent is required to use the best available
1114 inventory data each Project Report Period.

1115

1116 Project Proponents that select the inventory / modeling method must demonstrate in the Project
1117 Plan that the following requirements have been met:

- 1118
- A sensitivity analysis of modelled results to determine the key potential Sources of uncertainty and then evaluate the uncertainty associated with those Sources.
 - A justification for the approach to managing above uncertainties.
 - A conservative estimate of the Project Reductions.
 - Where a Project includes multiple Project Instances under a PoA, Project Instances must be homogenous, otherwise non-homogenous Project Instances must be measured sampled separately.

1119

1120

1121

1122

1123

1124

1125

1126

1127 As noted above, some minimum level of field measurement at the Project Site is required even
1128 where a Project Proponent is relying primarily on modelled results, to assist with minimizing the
1129 uncertainty associated with modelling, especially over time. The type and level of measurement
1130 is to be determined by the Project Proponent, and should be reflected in an overall assessment
1131 of uncertainty prepared by the Project Proponent. Such field measurement must be conducted at
1132 least once every 10 years, to align with the requirements of the Field Sampling Method, above.
1133 When sampling is conducted, results must be used to re-calibrate model results.

1134

1135 Project Proponents that select the inventory / modeling method must follow the same sampling
1136 requirements as the field sampling method.

1137

1138

1139

1140

1141 **8.1.1.2 Estimating Harvest Flow**

1142 The following requirements apply to estimating harvest flow and not to determine harvest volumes
1143 based on monitored harvest data.

1144
1145 For projects off and on Crown land, Project Proponents must demonstrate how they are
1146 accounting for climate-related risk in the short, medium, and long-term.

1147
1148 Baseline and Project harvest data must be included in meters cubed and hectares for each Project
1149 Report Period. Where a Project is a PoA, each Project Instance must itemize Baseline and Project
1150 harvest data in meters cubed and hectares for each Project Report Period.

1151 **8.1.1.2.1 Non-Crown Land Projects**

1152 For non-Crown land, Project Proponents must develop and justify an approach appropriate for
1153 their Project, and subject to requirements detailed elsewhere in this protocol. Project Proponents
1154 must provide evidence that harvest flow is consistent with local best practices, and in accordance
1155 with the Baseline Scenario candidate established in Section 5.2.1.

1156 **8.1.1.2.2 Crown Land Projects**

1157 During the Project Crediting Period, Project harvest data must be monitored by the Project
1158 Proponent and reported at each Project Report Period.

1159
1160 The Project Proponent must estimate sustainable harvest flows for the Baseline and Project
1161 Scenarios in accordance with timber supply analysis standards commonly used by Forest
1162 Analysis and Inventory Branch in Timber Supply Reviews in B.C. Timber supply Projections must
1163 be generated using methods that are documented and repeatable. The Project Proponent must
1164 demonstrate in the Project Plan that how the following principles have been met:

- 1165 a) The long-term harvest level must be sustainable, as indicated by a stable long-term total
1166 growing stock,
1167 b) Any declines in normal harvest levels in the short- to mid-term must be no more than or
1168 equal to 10% per decade,
1169 c) Any increase in timber supply from mid-term to long-term level must be less than or equal
1170 to 10% of normal harvest levels per decade, and
1171 d) Current AAC level must be maintained in the short-term, and be consistent with the
1172 principles a), b), and c) above. If the current AAC cannot be achieved while meeting
1173 principles a), b) and c), such as maximum 10% per decade rate of decline and maintaining
1174 the maximum mid-term level, Project documentation must provide justification. Such an
1175 explanation may simply be that any increase above the timber supply levels shown in the
1176 forecasts would result in disruption in the forecast during the specified time period. Note,
1177 this does not mean that the AAC must be used as the sole basis for harvest flow.

1178
1179 In the description above, short, medium and long-term have the following meanings:

- 1180 • Short-term – the first 20 years of the forecast.
1181 • Mid-term – the time period between the short and long terms.
1182 • Long-term – usually a period starting from 60 to 100 years from the Project Start Date,
1183 and is the time period during which the Projected harvest level is at the sustainable long-
1184 term level (which in turn is defined as the level that results in a flat total growing stock over
1185 the long term).

1186
1187 The same methodology for deriving the harvest flow must be used for both the Baseline and the
1188 Project (except where monitored Project data is being used and the Baseline is based on

1189 estimates), and the specific method must be documented (including quantities such as maximum
1190 allowable inter-period change in long-term growing stock in determining the long-term sustainable
1191 level and the inter-period change in Projected timber supply level).
1192

1193 8.1.1.3 Forest Carbon Model

1194 Estimates of forest carbon values by forest ecosystem carbon models may be performed by
1195 linking two or more models or with a single integrated model. Growth and yield models must be
1196 used to estimate values for existing and projected tree volume and other characteristics given
1197 starting conditions and site characteristics. Models used to estimate volume must have been used
1198 previously in B.C.'s Timber Supply Review. The Variable Density Yield Projection (VDYP), and
1199 Tree & Stand Simulator (TASS)/Table Interpolation for Stand Yields (TIPSY) are officially used in
1200 BC for province-wide growth and yield projections. TIPSY must be used for managed second
1201 growth stands, while the VDYP must be used for unmanaged natural stands. Minimum
1202 Operational Adjustment Factors (OAF) of OAF1 and OAF2 are 0.85 and 0.95, respectively.
1203 Growth and yield, forest inventory, and disturbance information used in the Carbon Budget Model
1204 (CBM-CFS3 (Kurz et al. 2009)) approximates national and forest management unit-level forest
1205 carbon accounting in Canada to estimate forest carbon values. The CBM-CFS3 is required for
1206 use in this Protocol. Model inputs (including data editors for climate, disturbance events and
1207 management activities, disturbance matrices, growth and yield curves, inventory, transition rules,
1208 default data, and all assumptions) must be included as appendices to the Project Plan.
1209

1210 The Province does not assume any liability in the case of model errors that affect Project
1211 Reductions.
1212

1213 Gaming or exploiting differences between models in Project planning is not acceptable. Validation
1214 Bodies and Verification Bodies must ensure the conservative and consistent use of model
1215 parameters and assumptions.
1216
1217

1218 8.1.2 PR8 Harvested Wood Products In-Use

1219 The method contains approaches for calculating carbon quantities in the HWP Reservoir for both
1220 North America (US and Canada) and offshore uses. Emission curves for both North American
1221 and offshore use, as well as for standard product mixes, specific Project are provided. Since a
1222 portion of the carbon initially stored in HWPs is known to be lost over time, the approach presented
1223 here involves assessing the amount of wood product carbon that is lost at various stages along
1224 the HWP lifecycle. The methodology uses separate data sets to estimate retention of HWP carbon
1225 Reservoirs for HWPs in North America, and offshore.

1226 Project Proponents must ensure that they include in their Project calculations any changes which
1227 may have been made to these resulting factors.

1228 The methodology described in this section applies to HWP In-Use Reservoirs, and does not
1229 consider storage within landfills or dumps. HWP sent to landfill is considered conservatively
1230 assumed to be emitted as CO₂ in this Protocol.
1231

1261

1262

1263

1264

An assessment of the amount of carbon stored in HWPs in-use over a 100-year period must include the following:

- Amount of carbon removed from the forest in harvested wood (net of on-site harvesting losses),
- Amount of carbon lost during production of wood products (e.g. at the sawmill, during the pulp and paper process, etc.) and assumed combusted (and emitted as CO₂ with minor amounts of CH₄ and N₂O) and/or otherwise aerobically lost to the atmosphere as CO₂,
- Amount of carbon in primary HWPs that remains in-use over the 100-year period,
- Amount of carbon in primary HWPs that does not remain in use for the full 100-year period but that is at some point combusted or sent to landfill and conservatively assumed to be emitted as CO₂,
- For HWPs in use in North America, quantification of these processes has been conducted by Natural Resources Canada in the NIR, quantifying carbon storage in HWPs in use, for B.C. forest products in North America and offshore.

1265

1266 The Project Proponent may choose one of the following two approaches for quantifying HWP
 1267 storage:

1268 1. **Default approach** – standard HWP mixes for both North American and offshore HWP
 1269 utilization.

1270 Using this approach, in-use is based on standard product mixes for North American and
 1271 offshore markets (See Table 2 below). This approach allows Project Proponents to
 1272 calculate HWP Reservoirs (determined in Equation 7) using standard tables.

1273
 1274 2. **Optional approach** – all harvested wood carbon is assumed to be immediately emitted
 1275 as CO₂. This approach is only available to Projects where the harvest is greater than or
 1276 equal to the harvest volumes of the Baseline Scenario.

1277
 1278 Harvest flow for both the Project and Baseline Scenario must be developed in accordance
 1279 with the requirements stipulated in Section 8.1.1.2.

1311 **Equation 8: Gross Mass of Carbon in Harvested Wood Products**

1312
$$GrossHWPCO2_d = RWBiomass_d \times f_{C,wood} \times \frac{MW_{CO_2}}{MW_C}$$

1313 Where,

Parameter	Description	Default Value
$GrossHWPCO2_d$	Mass of tCO ₂ e in delivered roundwood extracted from the Project Site during each Project Report Period, for each wood product destination <i>d</i> (i.e., North America or offshore). Measured in tCO ₂ e.	N/A
$RWBiomass_d$	Dry mass of the delivered roundwood extracted from the Project Site during each Project Report Period for each wood product destination <i>d</i> (i.e., North America or offshore). Measured in tonnes dry Biomass. Determined using Equation 9.	N/A
$f_{C,wood}$	Fraction of the dry mass of wood, excluding bark, that is carbon.	Assumed to be 50% for all wood species.
MW_{CO_2}	Molecular weight of CO ₂ .	44 g/mole
MW_C	Molecular weight of carbon.	12 g/mole

1314

1315 **Roundwood Biomass ($RWBiomass_d$)**

1316 Calculate or estimate volume of roundwood delivered to the mill (or exported), from the Project
 1317 Site, by species, year and wood product destination (NA or offshore). Harvest flow for both Project
 1318 and Baseline must be developed in accordance with the requirements stipulated in Section
 1319 8.1.1.2. Volumes must be for wood only (not including bark).

1320

1321 **Equation 9: Roundwood Biomass**

1322
$$RWbiomass_d = \sum_s vol_{s,d} \times wdf_s$$

1323

1324 Where,

Parameter	Description	Default Value
$RWBiomass_d$	Dry mass of the delivered roundwood extracted from the Project Site in each Project Report Period, for each wood product destination <i>d</i> (North America or offshore). Measured in tonnes dry Biomass.	N/A
$vol_{s,d}$	Volume of delivered roundwood in m ³ of species <i>s</i> for each wood product destination <i>d</i> , extracted from the Project Site in each Project Report Period.	N/A
wdf_s	Wood density factor for species <i>s</i> , from	Table 3

	Table 3. Measured in t/m ³ .

Sitka spruce (<i>Picea sitchensis</i>)	0.41

1328

1329

1330 **8.1.3 PE1 Fertilizer Production Emissions**

1331 Emissions from upstream fertilizer production are to be determined using Equation 10.

1332

1333

1334 **Equation 10: PE1 Fertilizer Production Emissions**

1335
$$T_{PE1} = \sum_f EF_f \times AL_f \times CF_f$$

1336 Where,

Parameter	Description	Default Value
T_{PE1}	Emissions from PE1 from fertilizer production that will be applied during each Project Report Period (tCO _{2e}).	N/A
EF_f	Emission factor for GHG and fertilizer type <i>f</i> .	See below
AL_f	Quantity of fertilizer of type <i>f</i> applied during each Project Report Period.	N/A
CF_f	Conversion factor to be used if the units of the activity level do not match those of the Emission factor for a particular fertilizer type <i>f</i> . Where both the activity level and Emission factor are expressed in the same units, CF would be set to 1.	N/A

1337

1338

1339 **Determining the Emission factor**

1340
 1341 Emission factors appropriate for the production of nitrogen-based fertilizers in question must be
 1342 selected from the Canadian NIR. In the event that an appropriate Emission factor is not included
 1343 in the NIR, the latest IPCC factor may be used. Otherwise, Emission factors found in peer
 1344 reviewed Sources relevant to the Project Site conditions may be used. A summary table of
 1345 Emission factors can be found in Appendix A.

1346
 1347 **Determining the activity level**

1348
 1349 Quantities of different types of fertilizer applied must be monitored during the Project.
 1350
 1351

1352 **8.1.4 PE2 Fertilizer Use Emissions**

1353
 1354 **N₂O Emissions from Fertilizer Use**

1355
 1356 N₂O Emissions that result from anthropogenic N inputs occur directly (from the soil to which N is
 1357 added) and indirectly: (i) volatilization and redeposition of nitrogen compounds, and (ii) leaching
 1358 and runoff of nitrogen compounds, mainly as nitrate. Both direct and indirect Emissions are
 1359 quantified for this SSR from the following sources:

- 1360 • Synthetic nitrogen fertilizer.
- 1361 • Organic nitrogen applied as fertilizer (e.g. manure, compost, and other organic soil
 1362 additives).

1363
 1364 Total N₂O Emissions related to fertilizer use is determined using the Equation 11.
 1365
 1366

1367 **Equation 11: PE2 Fertilizer Use Emissions**

1368 $T_{PE2} = N_2O_{direct} + N_2O_{indirect}$

1369
 1370 Where,

Parameter	Description	Default Value
T_{PE2}	Emissions from PE2 from nitrogen application within the Project Site during each Project Report Period (tCO ₂ e).	N/A
N_2O_{direct}	Direct Emissions of N ₂ O as a result of nitrogen application within the Project Site during each Project Report Period. Determined using Equation 12.	N/A
$N_2O_{indirect}$	Indirect Emissions of N ₂ O as a result of nitrogen application within the Project Site during each Project Report Period. Determined using Equation 15.	N/A

1371
 1372 **Direct N₂O Emissions**
 1373

1374 The direct nitrous oxide Emissions from nitrogen fertilization must be estimated using the following
 1375 equations:
 1376

1377
 1378
 1379

Equation 12: Direct Fertilizer Use Emissions

1380
$$N_2O_{direct} = [(M_{SN} \times (1 - Frac_{GASF}) + (M_{ON} \times (1 - Frac_{GASM})))] \times EF_{f,direct} \times \frac{MW_{N_2O}}{MW_N}$$

1381 Where,

Parameter	Description	Default Value
N_2O_{direct}	Direct Emissions of N ₂ O as a result of nitrogen application within the Project Site during each Project Report Period.	N/A
M_{SN}	Mass of synthetic fertilizer nitrogen applied, tonnes of N during each Project Report Period. Determined using Equation 13.	N/A
$Frac_{GASF}$	Fraction of Nitrogen that volatilizes as NH ₃ and NO _x for synthetic fertilizers.	0.1
M_{ON}	Mass of organic fertilizer nitrogen applied, tonnes of N during each Project Report Period. Determined using Equation 14.	N/A
$Frac_{GASM}$	Fraction of Nitrogen that volatilizes as NH ₃ and NO _x for organic fertilizers.	0.2
$EF_{f,direct}$	Emission factor for N additions from fertilizers, tonne N ₂ O-N / tonne N input.	0.010
MW_{N_2O}	Molecular weight of N ₂ O.	44 g/mole
MW_N	Molecular weight of N.	14 g/mole

1382

Equation 13: Fraction of Nitrogen that Volatilizes as NH₃ and NO_x for Synthetic Fertilizers

1384
$$M_{SN} = \sum_f M_{SF_f} \times NC_{SF_f}$$

1385 Where,

Parameter	Description	Default Value
M_{SN}	Mass of synthetic fertilizer nitrogen applied, tonnes of N during each Project Report Period.	N/A
M_{SF_f}	Mass of synthetic fertilizer of type <i>f</i> applied in during each Project Report Period, measured in tonnes.	N/A
$NC_{SF,f}$	Nitrogen content (mass fraction) of synthetic fertilizer type <i>f</i> applied.	N/A

1386

Equation 14: Fraction of Nitrogen that Volatilizes as NH₃ and NO_x for Organic Fertilizers

1388
$$M_{ON} = \sum_v M_{OF_v} \times NC_{OF_v}$$

1389
 1390 Where,

Parameter	Description	Default Value
-----------	-------------	---------------

M_{ON}	Mass of organic fertilizer nitrogen applied, tonnes of N in each Project Report Period.	N/A
M_{OFv}	Mass of organic fertilizer of type v applied in each Project Report Period, measured in tonnes.	N/A
NC_{OFv}	Nitrogen content (mass fraction) of organic fertilizer type v applied.	N/A

1391 Project Proponents must identify the nitrogen content for each synthetic and organic fertilizer
 1392 applied, as reported by the fertilizer manufacturer or determined by laboratory analysis.

1393
 1394 **Indirect N₂O Emissions**

1395
 1396 Indirect nitrous oxide Emissions from nitrogen fertilization are estimated using the following
 1397 equations:

1398
 1399
 1400 **Equation 15: Indirect Fertilizer Use Emissions**

1401
$$N_2O_{indirect} = (N_2O_{(ATD)} + N_2O_{(L)}) \times \frac{MW_{N_2O}}{MW_N}$$

1402
 1403 Where,

Parameter	Description	Default Value
$N_2O_{indirect}$	Indirect Emissions of N ₂ O as a result of nitrogen application within the Project Site during each Project Report Period.	N/A
$N_2O_{(ATD)}$	Amount of N ₂ O-N produced from atmospheric deposition of N volatilized, tonnes of N ₂ O in each Project Report Period. Determined using Equation 16.	N/A
$N_2O_{(L)}$	Amount of N ₂ O-N produced from leachate and runoff of N, tonnes of NO ₂ in each Project Report Period. Determined using Equation 17.	N/A
MW_{N_2O}	Molecular weight of N ₂ O.	44 g/mole
MW_N	Molecular weight of N.	14 g/mole

1404
 1405 **Equation 16: Amount of N₂O-N Produced from Atmospheric Deposition of N Volatilized**

1406
$$N_2O_{(ATD)} = [F_{SN} \times (Frac_{GASF}) + F_{ON} \times (Frac_{GASM})] \times EF_{ATD}$$

1407
 1408 Where,

Parameter	Description	Default Value
$N_2O_{(ATD)}$	Amount of N ₂ O-N produced from atmospheric deposition of N volatilized, tonnes of NO ₂ in each Project Report Period.	N/A
M_{SN}	Mass of synthetic fertilizer nitrogen applied, tonnes of N during each Project Report Period. Determined using Equation 13.	N/A
$Frac_{GASF}$	Fraction of Nitrogen that volatilizes as NH ₃ and NO _x for synthetic fertilizers.	0.1
M_{ON}	Mass of organic fertilizer nitrogen applied, tonnes of N in each Project Report Period. Determined using Equation 14.	N/A

$Frac_{GASM}$	Fraction of Nitrogen that volatilizes as NH_3 and NO_x for organic fertilizers.	0.2
EF_{ATD}	Emission Factor for N_2O Emissions from atmospheric deposition of N on soils and water surfaces, tonne N_2O-N / tonne N input.	0.01

1409 **Equation 17: Amount of N_2O-N Produced from Leachate and Runoff of N**

1410
$$N_2O_{(L)} = (F_{SN} + F_{ON}) \times Frac_{LEACH-(H)} \times EF_{(L)}$$

1411
1412 Where,

Parameter	Description	Default Value
$N_2O_{(L)}$	Amount of N_2O-N produced from leachate and runoff of N, tonnes of NO_2 in each Project Report Period.	N/A
M_{SN}	Mass of synthetic fertilizer nitrogen applied, tonnes of N in each Project Report Period. Determined using Equation 13.	N/A
M_{ON}	Mass of organic fertilizer nitrogen applied, tonnes of N in each Project Report Period. Determined using Equation 14.	N/A
$Frac_{LEACH-(H)}$	Fraction of N lost by leaching and runoff.	0.30 or 0 (see note)
$EF_{(L)}$	Emission factor for N_2O-N Emissions from N leaching and runoff, tonne of N_2O / tonne N input.	0.0075

1413
1414 The fraction of nitrogen lost by leaching and runoff ($Frac_{LEACH-H}$) applies only in those cases where
1415 soil water-holding capacity is exceeded as a result of precipitation or irrigation (i.e. precipitation
1416 is greater than evapotranspiration). Where this condition exists, the default value for $Frac_{LEACH-H}$
1417 = 0.30. Where evapotranspiration is greater than precipitation, the value for this parameter is zero.

1418
1419 Project Proponents for each calculation must identify the nitrogen content for each synthetic and
1420 organic fertilizer applied, as reported by the fertilizer manufacturer or determined by laboratory
1421 analysis.

1422
1423 **8.1.5 PE3 Biomass Combustion**

1424 Emissions from controlled burning of Biomass on-site, including burning of wood residuals and
1425 controlled burning for land clearing, and downstream manufacturing, etc., are to be determined
1426 using Equation 18.

1430

1431

1432

1433

1434

1435

1436

1437 **Equation 18: PE3 Biomass Combustion**

1438
$$T_{PE3} = \sum_b EF_b \times AL_b \times CF_b$$

1439 Where,

Parameter	Description	Default Value
T_{PE3}	Emissions from PE3 from Biomass combustion within the Project Site and downstream during each Project Report Period (tCO _{2e}).	N/A
EF_b	Emission factor for Biomass type <i>b</i> (e.g. tonnes CH ₄ , CO ₂ , and N ₂ O per tonne of Biomass burned).	See below
AL_b	Quantity of Biomass of type <i>b</i> combusted during each Project Report Period.	N/A
CF_b	Conversion factor to be used if the units of the activity level do not match those of the Emission factor for a particular Biomass type <i>b</i> . Note, special care must be taken to ensure that if the Emission factor and activity level do not assume the same moisture content of Biomass (often dry mass is assumed for Emission factors), an appropriate conversion factor is used based on measured or conservatively assumed Biomass moisture content. Where both the activity level and Emission factor are expressed in the same units, CF would be set to 1.	N/A

1440

1441 **Determining the activity level**

1442 Project Proponents must propose and justify an approach for determining the total mass of
1443 Biomass combusted during controlled burning events during a reporting period. The guidance
1444 given in Approach B in the VCS Module VMD0031, Estimation of Emissions from Burning should
1445 be used as a basis for developing a method. It is expected that such a method will be tailored to
1446 the standard operating practices of the Project Proponent. It must be possible to verifiably
1447 demonstrate that the method results in a conservative estimate of associated Project Emissions
1448 as compared to Baseline Emissions. Wherever possible, measured amounts of Biomass should
1449 be used (e.g. mass or volume of Biomass combusted), though it is recognized that in many cases
1450 (e.g. land clearing) such a measurement may not be possible and estimates based on site
1451 observations will be necessary.

1452

1453 The Project Proponent may either use monitored data or may estimate the amount of HWP
1454 produced using monitored quantities of wood sent to the processing facility and a B.C.-specific
1455 default production loss factor of 41%.

1456 **Determining the Emission factor**

1457 Some Biomass combustion Emission factors are available in the WCI 2011 Quantification
1458 Methodologies and must be used so long as the Emission factor selected is appropriate for the
1459 type of Biomass and conditions under which it is being combusted. Otherwise, Emission factors
1460 found in peer reviewed Sources relevant to the Project Site conditions may be used. Where more
1461 site specific data is not available, values from the Intergovernmental Panel on Climate Change

1462 Good Practice Guidance for Land Use, Land Use Change, and Forestry (Table 3A.1.16) (see
 1463 Appendix B: References) may be used. Where figures from Table 3A.1.16 are used, they must
 1464 be divided by 1000, to adjust the results from units of g/kg to units of t/t.
 1465

1466 8.2 BASELINE EMISSIONS AND REMOVALS

1467 Project Emission Reductions and Removal Enhancements are determined with Equation 19.

1468
 1469

1470 Equation 19: Total Baseline Emission Reductions or Removal Enhancements

1471 $\Delta GHG_{Baseline} = T_{(BR1\ to\ BR7)} + T_{BR8} - T_{BE1} - T_{BE2} - T_{BE3}$

1472
 1473

Where,

Parameter	Description	Default Value
$\Delta GHG_{Baseline,t}$	Total Emissions or Removals of CO ₂ e occurring in the Baseline during Project Report Period <i>t</i> (tCO ₂ e).	N/A
$\Delta T_{(BR1\ to\ BR7)}$	Emissions and Removals by Baseline live and dead forest carbon Reservoir (excluding HWP) during each Project Report Period (tCO ₂ e). Determined in Section 0.	N/A
T_{BR8}	Mass of CO ₂ stored in Baseline HWP) up to time since the last Project Report Period (tCO ₂ e). Determined in Section 8.2.2.	N/A
T_{BE1}	Emissions from BE1 from fertilizer production that will be applied during each Project Report Period (tCO ₂ e). Determined in Section 8.2.3.	N/A
T_{BE2}	Emissions from BE2 as a result of nitrogen application within the Project Site during each Project Report Period(tCO ₂ e). Determined in Section 8.2.4.	N/A
T_{BE3}	Emissions from BE3 from Biomass combustion during each Project Report Period (tCO ₂ e). Determined in Section 8.2.5.	N/A

1474
 1475

1476 8.2.1 BR1 to BR7 Live and Dead Forest Carbon Reservoirs (Excluding HWP)

1477 See Quantification Methodology for PR1 to PR7 in Section 7.0.

1479

1480 Estimating Harvest Flow

1481

1482 The Project Proponent must use the same method as the Project Scenario to estimate harvest
 1483 flow as described in Section 8.1.1.2.

1484
 1485

1486 8.2.2 BR8 Harvested Wood Products In-Use

1487 See Quantification Methodology for PR8 in Section 8.1.2.

1488

1489 **Determining an Activity Level**

1490
1491 In determining $RWBiomass_d$, for the Baseline Scenario, for species that are also harvested in the
1492 Project, the assumed HWPs produced from a given species must be the same as for the Project.
1493 For species harvested in the Baseline Scenario but not the Project, the Project Proponent must
1494 conservatively select and justify the HWPs produced from those species. Where the primary HWP
1495 produced cannot be identified for the Baseline Scenario, the HWP with the greatest overall
1496 storage in-use must conservatively be assumed.

1497
1498

1499 **8.2.3 BE1 Fertilizer Production**

1500 See Quantification Methodology for PE1 in Section 8.1.3.

1501
1502 **Determining the activity level**

1503
1504 Baseline fertilizer application must be estimated based on a justified application rate based on
1505 the practices described for the selected Baseline Scenario.

1506
1507

1508 **8.2.4 BE2 Fertilizer Use Emissions**

1509 See Quantification Methodology for PE2 in Section 8.1.4.

1510
1511 **Determining the activity level**

1512
1513 Baseline fertilizer application must be estimated based on a justified application rate based on
1514 the practices described for the selected Baseline Scenario.

1515
1516

1517 **8.2.5 BE3 Biomass Combustion**

1518 See Quantification Methodology for PE3 in Section 8.1.5.

1519
1520 **Determining the activity level**

1521 It must be possible to verifiably demonstrate that the method results in a conservative estimate of
1522 Baseline Emissions. Wherever possible, measured amounts of Biomass should be used (e.g.
1523 mass or volume of Biomass combusted), though it is recognized that in many cases (e.g. land
1524 clearing) such a measurement may not be possible and estimates based on site observations will
1525 be necessary.

1526

1527 **8.3 LEAKAGE**

1528 Leakage occurs when net increases in GHG Emissions occur outside the Project Site, as a result
1529 of the project activity.

1530 Where a risk of Leakage exists, Project Proponents may undertake Leakage mitigation measures
 1531 to reduce Leakage. If any significant increase in Emissions occurs as a result of these measures,
 1532 the resulting Emissions must be accounted using the methods given in Section 0 for the
 1533 appropriate Emission Source.

1534
 1535 There are two potentially relevant forms of Leakage that must be assessed:
 1536

- 1537 • L1 (Land Use-shifting Leakage), and
- 1538 • L2 (Harvest-shifting Leakage).

1539
 1540 Table 4 lists which Project types must assess which types of Leakage.
 1541

1542 **Table 4: Summary of potentially relevant Leakage types by Tenure type**

Project Type	Leakage Type	
	Land Use Shifting	Harvest-Shifting
AFF/REF	Internal only	No
CONS/IFM	Yes	Yes if Project harvesting < Baseline harvesting
AC	Yes	Yes

1543
 1544 Project Proponents will include a determination of Leakage in the Project Plan and Project Report.
 1545

1546 **8.3.1 L1 Land Use-shifting Leakage**

1547 Land Use-shifting Leakage (L1) is divided into two categories, and is determined with Equation
 1548 20:

- 1549 1) Internal land use Leakage, and
- 1550 2) External land use Leakage.

1551
 1552
 1553 **Equation 20: L1 Land use-shifting Emissions (Leakage)**

1554 $L1 = GHG_{CO2, Internal Land Use Leakage} + GHG_{CO2, External Land Use Leakage}$

1555
 1556 Where,

Parameter	Description	Default Value
<i>L1</i>	Net increase in Project Emissions due to Land Use-shifting Leakage from all affected carbon Reservoirs during each Project Report Period (tCO _{2e}).	N/A
$\Delta GHG_{CO2, Internal Land Use Leakage}$	Increase in Project Emissions due to internal deforestation during each Project Report Period (CO _{2e}). Determined below.	N/A
$\Delta GHG_{CO2, External Land Use Leakage}$	Increase in Project Emissions due to external Land Use-shifting Leakage during each Project Report Period (tCO _{2e}). Determined below.	N/A

1557
 1558

1559 **Determining GHG_{CO2}, Internal Land Use Leakage**

1560 Internal Land Use-shifting Leakage is deforestation shifting to other lands owned or controlled by
1561 the Project Proponent due to the Project.

1562
1563 Internal Land Use-shifting Leakage occurs where a Project Proponent decides to prevent the
1564 deforestation of a portion of their lands and establish CONS / IFM, and/or AC Project on those
1565 lands, while also deforesting another portion of land that they own, but which is outside the defined
1566 Project Site. Internal Land Use-shifting Leakage can also occur when part of a Project Proponents
1567 lands are afforested or reforested (AFF/REF), causing another part to be deforested.

1568
1569 Internal Land Use-shifting Leakage must be addressed by the Project Proponent as follows:

1570 i. For AFF, CONS / IFM, and AC Projects; Internal Land Use-shifting Leakage may be
1571 assumed to be zero if one of the conditions a, b, or c apply:

1572 a. Lands controlled by the Project Proponent outside the Project Site are not
1573 Forest land,

1574 b. Covenants, easements, existing right of ways, or other restrictions are in place
1575 on all Forest lands controlled by the Project Proponent outside the Project Site
1576 for as long as those restrictions remain in place and to the extent that these
1577 restrictions demonstrate that Leakage is zero, and/or

1578 c. Demand for the land use that may cause Leakage in the Baseline Scenario is
1579 satisfied or removed or due to the actions of the Project Proponent (it is
1580 possible that a Project Proponent will not be able to demonstrate this initially
1581 but may be able to do so at some point during the Project).

1582 ii. Otherwise, justify an appropriate geographic area for assessment of Land Use-shifting
1583 Leakage, considering economic and other relevant factors affecting demand for land-
1584 use types in the Baseline Scenario affected by the Project, given that land use demand
1585 is typically local in nature (e.g. demand for housing, commercial land, etc.). A Project
1586 Proponent may skip this step by including all land that they own or control within the
1587 assessment area.

1588 In each Project Report, the Project Proponent must report on any deforestation activities that have
1589 occurred within the assessment-area and where the Project Proponent owns or controls the land,
1590 where the new land use is equivalent to the Project's land use in the Baseline Scenario. Where
1591 such deforestation is identified, the decrease in stored carbon that occurs as a result of the
1592 deforestation, must be assessed using Equation 21. Net decreases associated with that
1593 deforestation activity must be recorded as an affected land use shifting Emission for the Project.
1594 Internal Land Use Leakage is equal to the net decrease in forest carbon Reservoirs due to
1595 deforestation lands owned or controlled by the Project Proponent, as indicated in Equation 21.

1607

Equation 21: Internal Land Use Leakage $GHG_{CO_2, Internal Land Use Leakage}$

1608 $\Delta GHG_{CO_2, Internal Land Use Leakage} = (\Delta T_{(DR1 to DR7)}) - (\Delta T_{(NDR1 to NDR7)})$

1609 Where,

Parameter	Description	Default Value
$\Delta GHG_{CO_2, Internal Land Use Leakage}$	Total increase in Project Emissions due to internal deforestation during each Project Report Period(CO ₂ e).	N/A
$\Delta T_{DR1 to DR7}$	Emissions due to deforestation by live and dead forest carbon Reservoirs (excluding HWP) (tCO ₂ e). Determined similar to Equation 3 for the Project. For the end of each Project Report Period.	N/A
$\Delta T_{NDR1 to NDR7}$	Non-deforested Emissions and Removals by live and dead forest carbon Reservoirs (excluding HWP) (tCO ₂ e). Determined similar to Section 0 for the Baseline. For the end of each Project Report Period.	N/A

1610

1611 **Determining $GHG_{CO_2, External Land Use Leakage}$**

1612 External Land Use-shifting Leakage is deforestation of lands outside the ownership or control of
1613 the Project Proponent due to the Project. External land use Leakage only needs to be addressed
1614 for AC Projects as follows:

1615

1616 i. External land use Leakage may be assumed to be zero if it can be verifiably shown that
1617 demand for the land use in the Baseline Scenario is satisfied or removed in some way by
1618 or due to the actions of the Project Proponent that does not lead to deforestation outside
1619 of the Project Site.

1620 ii. Otherwise, using the Local Study Area for assessment (see Section 4.04.2), considering
1621 economic and other relevant factors affecting demand for land-use types in the Baseline
1622 Scenario affected by the Project, given that land use demand is typically local in nature
1623 (e.g. demand for housing, commercial land, etc.).

1624

1625 A Leakage-assessment must consider, at minimum, the following:

- 1626 • The state of supply and demand for the land use in the Baseline Scenario type,
1627 including historic trends over the past 5 years, the current situation, and a
1628 projection forward of anticipated future trends over the Project’s Project Crediting
1629 Period (25 years as per the Regulation),
- 1630 • All local zoning bylaws and other restrictions on land development such as
1631 covenants, easements, and existing right of ways,
- 1632 • Community development plans and regional growth strategies,
- 1633 • There are restrictions in place such that there is no opportunity for the land use in
1634 the Baseline Scenario to shift to other Forest land within the Leakage-
1635 assessment-area. Consequently, the demand for land will remain unfilled (note,
1636 zoning restrictions are likely not sufficient to demonstrate this, as zonings may be
1637 changed based on applications by developers, and land use plans), and
- 1638 • Availability of Forest land (private, municipal, Crown-owned, First Nations,
1639 reserves, or other) that might be suitable for the land use in the Baseline Scenario,
1640 subject to the above assessment of zoning, plans and strategies, but with
1641 consideration of the potential for zoning changes to occur that might permit

1642 additional Forest lands to be eligible for deforestation and conversion to the land
 1643 use in the Baseline Scenario type.
 1644 The External Land Use-Shifting Leakage assessment must be prepared by a Designated
 1645 Member of the Appraisal Institute of Canada and must accompany an assessment of the
 1646 suitability of the land for the conversion required in Section 3.2.3.

1647

Guidance Note: The use of average development rates for lands over a broad geographic area (e.g. all of B.C.) will not be appropriate for assessing Leakage, as by definition, a AC Project is occurring in an area of sufficient non-Forest land use demand that the deforestation Baseline can be justified. It is likely that local land use demand will exceed average land use demand across a broader area.

1648

1649 Based on the results of this assessment, the Project Proponent must verifiably provide a
 1650 conservative assessment of the quantity of Emissions that would occur from affected carbon
 1651 Reservoirs, based on the per hectare Removals to be achieved by the Project from forest
 1652 carbon Reservoirs relative to the Baseline Scenario over the Project Crediting Period in
 1653 Equation 22. The deforested hectares developed must reflect that assessed likelihood / risk that
 1654 Leakage might occur.

1655

1656

1657 **Equation 22: Net decrease in forest carbon Reservoirs due to deforestation lands not**
 1658 **owned or controlled by the Project Proponent**

1659
$$\Delta GHG_{CO2, External Land Use-shifting Leakage} = \frac{(\Delta T_{(PR1 to PR7)}) - (\Delta T_{(BR1 to BR7)})}{Ha_{Project Site}} \times Ha_{deforested hectares}$$

1660 Where,

Parameter	Description	Default Value
$\Delta GHG_{CO2, External Land Use-shifting Leakage}$	Net increase in Project Emissions due to external Land Use-shifting Leakage during each Project Report Period.	N/A
$\Delta T_{(PR1 to PR7)}$	Emissions and Removals by Project live and dead forest carbon Reservoir (excluding HWPs) during each Project Report Period (tCO ₂ e). Determined using Equation 4.	N/A
$\Delta T_{(BR1 to BR7)}$	Emissions and Removals by Baseline live and dead forest carbon Reservoir (excluding HWPs) during each Project Report Period (tCO ₂ e). Determined in Section 0.	N/A
$Ha_{Project Site}$	Area of the AC Project (ha).	N/A
$Ha_{Deforested hectares}$	Area of deforestation expected outside the Project Site and not owned or controlled by the Project Proponent in each Project Report Period.	N/A

1661

1662

1663 8.3.2 L2 Harvest-shifting Leakage

1664 Harvest Leakage occurs when there is an increase in GHG Emissions from areas outside the
 1665 Project Site, which occurs as a result of the Project reducing production of a commodity, causing
 1666 a change in the supply and market demand equilibrium, resulting in a shift of production elsewhere
 1667 to make up for the lost supply.

1668 For Projects that are required to assess both Land Use-shifting Leakage and Harvest-shifting
1669 Leakage, Land Use-shifting Leakage must be assessed first. Harvest-Shifting Leakage is to be
1670 assessed based only on the amount of decreased Project harvesting relative to the Baseline
1671 Scenario that is not already accounted for by Land Use-shifting Leakage.

1672 Harvest-shifting Leakage must only be assessed in a given Project Report Period where Project
1673 HWP production, in terms of amount of carbon or carbon dioxide stored, is less than HWP
1674 production in the Baseline Scenario. Where HWP production in the Baseline Scenario is zero
1675 (e.g. typically in AFF/REF Projects), Harvest-shifting Leakage would be zero. In AC Projects, the
1676 Baseline Scenario include harvesting until the lands in the Baseline Scenario have been fully
1677 developed and further deforestation ceases.

1678
1679 AC Projects with the potential for both Land Use-shifting and Harvest-shifting Leakage, Harvest-
1680 shifting Leakage is to be assessed based only on the amount of decreased Project harvesting
1681 relative to the Baseline Scenario that is not already represented in the assessed amount of Land
1682 Use-shifting Leakage. For example, if half of the deforestation in the Baseline Scenario avoided
1683 by a Project at the Project Site is determined to shift to other areas outside of the Project due to
1684 non-Forest land use demand, Harvest-shifting Leakage would only be assessed on the portion of
1685 AC (i.e. avoided harvesting) that would not have shifted to other areas due to non-Forest land use
1686 demand. For internal Harvest-shifting Leakage, this must be factored into the analysis conducted
1687 by the Project Proponent, External Harvest-shifting Leakage has been explicitly factored into the
1688 equations provided below.

1689
1690 Two options are available for Project Proponents to determine Harvest-shifting Leakage;
1691 assessing the total change in carbon all Reservoirs, or assessing the total change in harvesting
1692 in affected Reservoirs. The estimate approach may not be revised once established in the Project
1693 Plan.

1694

1695 [8.3.2.1 Harvest-shifting Leakage \(Option 1 – Change in Forest Carbon Reservoirs\)](#)

1696 This approach uses the total change in forest carbon Reservoirs in a Project Report Period, rather
1697 than just the change associated with harvesting, as the basis for the external harvesting Leakage
1698 calculation. This approach is most suitable for Projects that reduce the amount of harvesting
1699 relative to the Baseline Scenario without undertaking any other changes to forest management
1700 practices.

$\Delta GHG_{CO2, Internal Harvest-shifting}$	Increase in Project Emissions due to internal Harvest-shifting Leakage during each Project Report Period. See below.	N/A
$\Delta GHG_{CO2, Harvesting}$	Net incremental mass of CO ₂ removed from the Project forest during each Project Report Period compared to the Baseline Scenario (tCO ₂ e), via the following mechanisms: <ul style="list-style-type: none"> • Physical Removal of harvested wood from the Project forest. • Harvesting-related losses that occur within the forest (e.g. lost branches, tops, etc.) that are assumed to rapidly decay and release CO₂ to the atmosphere. • Biomass combustion. Determined using Equation 27.	N/A
$\Delta GHG_{CO2, R, HWP}$	Net incremental mass of CO ₂ stored in Project Reservoir R HWPs harvested during each Project Report Period that will endure for a period of 100 years as compared to the Baseline Scenario (tCO ₂ e). Determined using Equation 25.	N/A
L1	Net increase in Project Emissions due to Land Use-shifting Leakage from all affected carbon Reservoirs during each Project Report Period (tCO ₂ e). Determined using Equation 20.	N/A
$\%Leakage_{External Harvest-shifting}$	Increase in Project Emissions due to external Harvest-shifting Leakage during each Project Report Period, expressed as a percentage of the net Removals that is expected to shift to lands outside the ownership or control of the Project Proponent over the Project Report Period. See Section 8.3.2.3.1 or Section 8.3.2.3.2 below.	N/A

1767

1768

1769 As with Land Use-shifting Leakage, Harvest-shifting Leakage is divided into two categories:
 1770 Internal Harvest-shifting Leakage and External Harvest-shifting Leakage

1771

1772 **Determining Internal Harvest-shifting Leakage ($GHG_{CO2, Internal Harvest-shifting}$)**

1773 Internal Harvest-shifting Leakage refers to the shifting to other lands owned or controlled by the
 1774 Project Proponent.

1775

1776 Internal Harvest-shifting occurs where a Project Proponent decides to reduce harvesting on a
 1777 portion of their lands and establish a Project while increasing harvesting on another portion of
 1778 land that they own, but which is outside the defined Project Site.

1779

1780 Internal Harvest-shifting Leakage is to be addressed by the Project Proponent in each Project
1781 Report Period as follows:

1782 i. If it can be verifiably shown that demand for harvested wood that is no longer harvested
1783 by the Project is satisfied or removed in some way by or due to the actions of the Project
1784 Proponent, then Internal Harvest-shifting Leakage can be assumed to be zero for the
1785 remainder of the Project (it is possible that a Project Proponent will not be able to
1786 demonstrate this initially but may be able to do so at some point during the Project).

1787 ii. Assess the opportunities for increasing harvesting on other lands owned or controlled by
1788 the Project Proponent by:

1789 a. For Crown land licensed by the Project Proponent, report on the difference between
1790 current harvesting levels and the annual allowable cut in all Timber Supply Areas
1791 (TSAs) and Tree Farm Licence (TFL) areas for which the Project Proponent holds a
1792 license. In the case of TSAs, this may require the consideration of land not controlled
1793 by the Project Proponent, but that still falls within a TSA in which the Project
1794 Proponent holds a license (for the purposes of this Internal Harvest-shifting Leakage
1795 assessment, such lands will be considered owned or controlled).

1796 b. For private land, assess the extent to which other Forest land owned or controlled by
1797 the Project Proponent could be harvested (which could consider the existence of land
1798 covenants that would prohibit harvesting).

1799 If there are no opportunities for further harvesting identified, then Internal Harvest-shifting
1800 Leakage may be assumed to be zero.

1801 iii. If opportunities for increased harvest are identified, then the Project Proponent has two
1802 options:

1803 a. Expand the Project Site to encompass areas with additional harvesting potential,
1804 thereby bringing all potential Sources of Internal Harvest-shifting Leakage within the
1805 controlled SSRs of the Project, and assume Internal Harvest-shifting Leakage is zero,
1806 or

1807 b. Prepare a report that assesses the extent to which internal Harvest-shifting Leakage
1808 has occurred, by considering historic harvesting amounts per hectare per year on all
1809 owned and controlled lands outside of the Project Site for the 5 years prior to the start
1810 of the current Project Report Period and all years within the current Project Report
1811 Period as well as regional or provincial trends in amounts of harvesting over the same
1812 timeframe (with the selected geographic area to be justified by the Project
1813 Proponent). Where owned and controlled harvesting trends indicate that harvesting
1814 has increased relative to regional or provincial trends, and where these increases
1815 cannot be explained by factors independent from the Project, Internal Harvest-
1816 shifting Leakage is to be assessed as the minimum of:

1817 • The difference between owned and controlled harvesting per hectare per year
1818 and regional or provincial harvesting per hectare per year multiplied by the total
1819 hectares of owned and controlled forest outside of the Project Site and by the
1820 number of years in the Project Report Period,

1821 • The maximum potential amount of increased harvesting that could occur over the
1822 Project Report Period based on the assessment described in ii.a., above, and,

1823 • The total amount of decreased harvesting that occurred due to the Project
1824 relative to the Baseline during the current reporting period plus decreases in
1825 harvesting between the Project and Baseline for the five years prior to the start
1826 of the current reporting period minus any internal Harvest-shifting Leakage
1827 assessed against the Project due to decreased harvesting in the five years prior
1828 to the start of the current reporting period.

1829
1830

1831 **Equation 27: In-forest harvesting impacts (for Harvest-shifting Leakage Option 2)**

1832 $\Delta GHG_{CO_2, Harvesting}$

1833
$$= \left[\sum_s (M_{s,baseline} \div Harvest\ Efficiency_s) \right.$$

1834
$$\left. - \sum_s (M_{s,project} \div Harvest\ Efficiency_s) \right] \times f_{C,wood} \times \frac{MW_{CO_2}}{MW_C}$$

1835 Where,

Parameter	Description	Default Value
$\Delta GHG_{CO_2, Harvesting}$	Net incremental mass of CO ₂ removed from the Project forest during each Project Report Period as compared to the Baseline Scenario, via the following mechanisms: <ul style="list-style-type: none"> Physical Removal of harvested wood from the Project forest. Harvesting-related losses that occur within the forest (e.g. lost branches, tops, etc.) that are assumed to rapidly decay and release CO₂ to the atmosphere. Biomass combustion. 	N/A
$M_{s,Baseline}$	Dry mass of harvested wood, minus bark, harvested in the Baseline during each Project Report Period that will be processed into HWP. Measured in tonnes dry Biomass. This value is determined in a manner analogous to $RWBiomass_d$ in Equation 9, except that this mass is determined by species rather than by HWP type.	N/A
$Harvest\ Efficiency_s$	The ratio of $M_{s,Baseline}$ to total woody dry mass of a tree of species s prior to harvest. See below.	See below.
$M_{s,Project}$	Dry mass of harvested wood, minus bark, harvested in the Project during each Project Report Period that will be processed into HWP. Measured in tonnes dry Biomass. This value is determined in a manner analogous to $RWBiomass_d$ in Equation 9, except that this mass is determined by species rather than by HWP type.	N/A
$f_{C,wood}$	Fraction of the dry mass of wood, excluding bark, that is carbon.	Assumed to be 50% for all wood species.
MW_{CO_2}	Molecular weight of CO ₂ .	44 g/mole
MW_C	Molecular weight of carbon.	12 g/mole
s	Relevant tree species types being harvested in the Project and Baseline area.	N/A

1836

1837 **Determining Harvest Efficiency_s**

1838 The Project Proponent will be responsible for justifying harvesting efficiencies appropriate for the
1839 Project and Baseline Scenario.

1840 Harvesting efficiency is determined by considering tree species (s) involved, typical age of trees
1841 at harvest, and any other relevant factors. A Project Proponent may choose to use a single harvest
1842 efficiency value, rather than one for each relevant species, as long as the approach is
1843 demonstrated to be conservative (i.e. does not under-estimate Leakage).

1844

1845

1846 **External Harvest-shifting Leakage (%Leakage_{External Harvest-shifting})**
1847 External Harvest-shifting Leakage refers to the shifting to other lands outside the ownership or
1848 control of the Project Proponent.

1849
1850 If it can be verifiably shown that demand for wood products that are no longer produced by the
1851 Project relative to the Baseline Scenario during the Project Report Period is satisfied or removed
1852 in some way by or due to the actions of the Project Proponent that does not involve increasing
1853 harvesting outside the Project Site, then External Harvest-shifting Leakage may be assumed to
1854 be zero for that Project Report Period. Otherwise, External Harvest-shifting Leakage must be
1855 assessed in a manner consistent with Section 8.3.2.1.

1857 8.3.2.3 External Harvest-Shifting Leakage

1858 To determine the external harvesting-shifting Leakage factor, two options are provided:

- 1859
- 1860 1) Provincial default Leakage factor estimates (Option 1), and
 - 1861 2) Project-specific external Harvest-shifting Leakage factor (Option 2)

1862
1863 A Project Proponent may use either approach (subject to any restrictions noted below). However,
1864 where a Project Proponent decides part way through the Project to change from the use of a
1865 Project-specific approach to the use of provincial default estimates and such a change is likely to
1866 result in a lower assessed amount of Leakage going forward, the Project Proponent must estimate
1867 the extent to which the default value underestimates Leakage relative to the Project-specific case
1868 based on historic Project data and provincial default estimates, and adjust the provincial default
1869 results going forward accordingly to minimize the likelihood of the final Leakage assessment
1870 underestimate what the Project-specific approach would have likely determined. The Project
1871 Proponent must also consider if, and to what degree, the historic Project-specific approach
1872 overestimated actual historic Leakage based on retroactive market and other data, and adjust the
1873 estimate accordingly.

1874 8.3.2.3.1 Provincial default external Harvest-shifting Leakage estimates

1875 The Project Proponent may use provincial default Leakage estimate from Table 5 below for their
1876 Project Leakage estimate provided that the value is supported by a statement of acceptance that
1877 the Project is representative of average timber commodities and the Project Proponent has no
1878 reason to believe Leakage would be higher than the provincial default Leakage estimate.

1879
1880
1881 **Table 5: Provincial default external Harvest-shifting Leakage estimates (%Leakage_{External}**
1882 **Harvest-Shifting)**

Geographic Area	Estimated Leakage
Northern Interior	71.89%
Southern Interior	69.18%
Coast	47.37%

1883
1884 The default Leakage factors referenced in the above table have been derived using the Project-
1885 specific approach based on the average mix of tree species in the total harvest of each respective
1886 geographic area (see Appendix C: Project-specific external Harvest-Shifting Leakage
1887 Determination). There are certain tree species in specific regions of B.C., which are less
1888 substitutable in terms of developing certain wood products than others. The substitutability of
1889 wood products has a significant effect on the ultimate Leakage estimate. The Project Proponent

1890 should use the provincial default Leakage estimates as a guide. When Project Sites have
1891 proportions of tree species that differ from the default averages and perhaps higher proportions
1892 of tree species with low or moderate substitutability than what is reflected in the default for the
1893 Project's Site, it is recommended that the Project Proponent utilize the guidance indicated in this
1894 document adjust the Leakage estimates to reflect these Project Specifics accordingly.

1895 **8.3.2.3.2 Project-specific external Harvest-shifting Leakage estimates**

1896 The Project Proponent may estimate Project Specific Leakage rates using the methodology in
1897 Appendix C: Project-specific external Harvest-Shifting Leakage Determination.

1898
1899

1900 **8.4 REVERSALS AND THE CONTINGENCY ACCOUNT**

1901 The Regulation requires that the Project Proponent of sequestration Projects ensure that the
1902 Project Removals remain Permanently sequestered. For the purposes of this Protocol, 100 years
1903 after the Crediting Period ends is considered Permanent.

1904

1905 Other agreements in addition to this Protocol (i.e. Atmospheric Benefit Agreements or
1906 Atmospheric Benefit Sharing Agreements) with government may require additional deductions
1907 (see Equation 1).

1908

1909

1910 **8.4.1 Monitoring and Maintenance Plan for Reversals during and after the**
1911 **Project**

1912 Project Proponents must provide a Monitoring and Maintenance Plan which (along with data
1913 collection considerations included in Section 10.0) includes descriptions on how Risk of Reversal
1914 will be managed throughout the Crediting Period and Monitoring Period.

1915

1916 In addition to the identification of each risk below, the Project Proponent must document how
1917 each risk will be monitored, mitigated (if applicable - see Appendix H) and reported on in a time
1918 period consistent with the Project Report Periods and Monitoring Periods:

1919

- Financial risk
- Fire risk
- Drought risk
- Pest and disease risk
- Wind risk
- Hydrological or flooding risks
- Geomorphic and/or geological risks

1920

1921

1922

1923

1924

1925

1926 Assumptions used to inform the Monitoring and Maintenance Plan must use peer-reviewed
1927 research, government publications (from the Government of Canada or Government of B.C.), or
1928 data from within 10 years.

1929

1930 Reversal Monitoring must be described in detail as part of the Project design and Project
1931 Monitoring procedures in the Project Plan.

1932

1933

1934

1935

1936 **8.4.2 Identifying a Reversal**

1937 Reversals are a decrease in the Project Reservoir whereby the amount of Emissions released
1938 exceeds the number of Removal Enhancements that occur when carbon stocks associated with
1939 issued Offset Units are released to the atmosphere in a Project Report Period. In other words, a
1940 Reversal is a disturbance where the sum of the selected SSRs including Leakage under Baseline
1941 and Project Scenarios is negative. The Project Proponent must demonstrate through verification,
1942 that carbon stocks associated with previously issued Offset Units from Emission Reductions or
1943 Removal Enhancements are maintained for 100 years.

1944
1945 Reversals occur where there has been a loss of forest carbon stocks, i.e., a release to the
1946 atmosphere of carbon dioxide, that was not included as part of the Emissions modeling, across
1947 the Project Site as opposed to a stand-by-stand basis. Reversals may also occur in cases where
1948 the Project Proponent was negligent in their Project responsibilities that led to the Reversals, e.g.,
1949 not adhering to the Monitoring requirements of the Project Plan. Reversals as a result of provincial
1950 government decision-making on Crown land are not considered Reversals, and are instead
1951 handled through negotiated contracts between the Crown and the Project Proponent.

1952
1953 Disturbances and harvesting that are anticipated to occur on a predictable basis for the project
1954 area shall be included within the modeling of the Project and Baseline. Where harvesting in a
1955 Project Report Period exceeds Baseline harvesting in that same period, a Reversal has
1956 occurred.

1957
1958 Reversals can be caused by wildfire, disease/insects, third party illegal harvesting beyond the
1959 control of the Project Proponent e.g. theft, or any other event that were caused by natural,
1960 unintended forces. Forests are subject to a variety of natural disturbances that reduce growth and
1961 carbon storage. The Risk of Reversal is determined in Appendix H: Risk of Reversal
1962 Determination.

1963
1964 Changes to assumptions of climate variability, which was built into original modelling, but was
1965 revised throughout Project Reporting periods will see retirements of units from the Contingency
1966 Account should a material loss of the Primary Activity Reservoir occur.

1967
1968

1969 **8.4.3 During Project Crediting Period**

1970

1971 **8.4.3.1 Notifying of a Reversal**

1972 For all Reversals, the Project Proponent must notify the Director, in writing, of the Reversal and
1973 provide a description and the nature of the Reversal within 30 calendar days of its discovery.

1974

1975 **8.4.3.2 Reporting of a Reversal**

1976 Project Proponents that have identified an event meets the definition of a Reversal must complete
1977 the Reversal Report Appendix on the Government-approved Project Report template at each
1978 Project Report Period.

1979

1980

1981

1982 **8.4.3.3 Verifying Reversal Determination**

1983 The Project Proponent must itemize all Reversals in the Project Report. Assessment of the impact
1984 of a Reversal must be consistent with the same field sampling, modeling, and/or quantification
1985 procedures employed by the Project for assessing Project and Baseline Emissions and Removal
1986 Enhancements.
1987

1988 **8.4.3.4 Project and Baseline Scenario Adjustments**

1989 Once a Reversal occurs, the Project and Baseline Scenarios must be adjusted for subsequent
1990 Project Reports. Furthermore, Offset Units may not be claimed resulting from sequestration from
1991 natural regeneration
1992

1993 The impact of the Reversal on forest carbon must, in addition to being assessed for the Project,
1994 also be modeled for the Baseline Scenario (except where the Baseline is non-Forest land such
1995 as in AFF or AC where the Project Site is non-forest at the start of the Crediting Period).
1996

1997 Modeling must include observations of the type and extent of Reversal experienced by the
1998 Project, as well as assumptions regarding the Baseline Scenario. In preparing the revised
1999 Baseline model, the Project Proponent must demonstrate in the Project Report how the model
2000 will provide a conservative estimate of the Baseline (i.e. does not overstate the impact of the
2001 Reversal on the Baseline) to manage the uncertainty of predicting the impact of a particular
2002 Reversal on a hypothetical Baseline Scenario.
2003

2004 **8.4.4 After Project Crediting Period**

2005 The Project Proponent must follow the same approach as during the Project Crediting Period
2006 addressing a Reversal with the exception that reporting the Reversal(s) must occur at the next
2007 required Monitoring Report. More Monitoring Report requirements can be found in Section 10.1.

2008

2009 **8.4.5 Contingency Account**

2010

2011 **8.4.5.1 Contributions to Contingency Account**

2012 To mitigate the risk of potential Reversals described in this section, Project Proponents are
2013 required to contribute a percentage of the net Removal Enhancements and Emission Reductions
2014 at each Offset Unit issuance to the B.C. Contingency Account.

2015 **8.4.5.1.1 Contingency Account Details**

2016 The B.C. Contingency Account is a holding account into which the Director issues Offset Units in
2017 accordance with Section 13(4)(c) of the Act. When issuing Offset Units based upon Project
2018 Reports and Verification Statements for forest carbon sequestration and storage Projects, the
2019 Director issues a specified volume of verified Offset Units into the Contingency Account to account
2020 for the Risk of Reversal. In accordance with the Regulation Section 24(2), up to 51% of the Offset
2021 Units issued in relation to a sequestration and storage Project may be required to be credited to
2022 the Contingency Account. Each sequestration or storage Project's contribution of Offset Units to
2023 the Contingency Account is determined, asserted and verified using a Risk of Reversal described

2024 in Section 8.4.5.2. If a Sequestration Project experiences a Reversal of an Emission Reduction
 2025 and/or Removal Enhancement, the Director will retire from the Contingency Account a number of
 2026 Offset Units equal to the amount that have been reversed. The purpose of the Contingency
 2027 Account is to act as a form of insurance and to maintain environmental integrity of the program.
 2028

2029 **8.4.5.2 Risk of Reversal**

2030 The purpose of determining the Risk of Reversal of a Project is to determine the likelihood and
 2031 magnitude that a Reversal will occur up to 100 years after the Crediting Period ends. The Risk of
 2032 Reversal is based upon Project-specific attributes and must be determined using the approach
 2033 described in Appendix H: Risk of Reversal Determination. Once established, the Risk of Reversal
 2034 is multiplied against the Project Reductions to determine the portion of Offset Units that the
 2035 Director will issue into the Contingency Account. See Equation 28 for more details.
 2036
 2037

2038 **Equation 28: Determining Contingency Account Remittance**

2039 $CON_{\beta} = \beta \times [\Delta GHG_{net} - L1 - L2]$
 2040
 2041

Where,

Parameter	Description	Default Value
CON_{β}	Contributions to the Contingency Account by the Project Proponent during each Project Reporting period. Expressed as tCO _{2e} .	N/A
β	Percentage of units contributed to the Contingency Account at each Project Report Period. Determined in Appendix H: Risk of Reversal Determination.	N/A
ΔGHG_{net}	Net incremental Emission Reductions and Removal Enhancements of CO _{2e} before deductions, achieved by the Project during the Project Report Period as compared to the Baseline (tCO _{2e}). A net increase in Emission Reductions and Removal Enhancements is expressed as a positive number. Determined using Equation 2.	N/A
$L1$	Net increase in Project Emissions due to Land Use-shifting Leakage from all affected carbon Reservoirs during each Project Report Period (tCO _{2e}). Determined using Equation 20.	N/A
$L2$	Net increase in Project Emissions due to Harvest-shifting Leakage from all affected carbon Reservoirs during each Project Report Period (tCO _{2e}). Determined in Section 0.	

2042
 2043

2044 **8.4.5.3 Compensating for a Reversal**

2045 The Contingency Account is designed to account for Reversals only. Upon submission of the
 2046 Project Report or Monitoring Report and in the case where an Reversal has occurred, the Project
 2047 Proponent must make a request to the Director to retire Offset Units held in the contingency
 2048 account in an amount equal to the verified Reversal estimate in the Project Report or Monitoring
 2049 Report. At the discretion of the Director, the Director may retire Offset Units in accordance with
 2050 the Regulation.
 2051

2052 The Director may also withhold future issuances Offset Units until the accepted number of Offset
2053 Units have been retired from the Contingency Account.
2054 In the event that a Reversal occurs for a Project Instance within a PoA, the Project Proponent
2055 must make a request to the Director to retire Compliance Units held in the Contingency Account
2056 on behalf of all aggregated Project Instances.
2057

2058 8.4.5.4 Termination of a Project

2059 If Reversals exceed the amount remitted to the Contingency Account over the Project to date, the
2060 number of offsets allocated in the Contingency Account for that Project reaches zero. In that
2061 instance, the Project is terminated. Depending on the Project type and the nature of the
2062 disturbance, a new Project may be established.
2063
2064

2065 8.5 PROJECT REDUCTIONS

2066 A summary of equations used to determine Emission Reductions and Removal Enhancements is
2067 below.

2068

<i>L1</i>	Net increase in Project Emissions due to Land Use-shifting Leakage from all affected carbon Reservoirs during each Project Report Period (tCO _{2e}). Determined using Equation 20.	N/A
<i>L2</i>	Net increase in Project Emissions due to Harvest-shifting Leakage from all affected carbon Reservoirs during each Project Report Period (tCO _{2e}). Determined in Section 0.	N/A
CON_{β}	Contributions to the Contingency Account during each Project Report Period. Expressed as tCO _{2e} . Determined using Equation 28.	N/A
<i>Other deductions</i>	Other deductions established in an Atmospheric Benefits Agreement, Indigenous Atmospheric Benefit Agreement, Atmospheric Benefits Sharing Agreement, or other contractual obligations (if relevant) (tCO _{2e}).	N/A

2115

2116

9.0 PROJECT ESTIMATES

2117

2118 In accordance with Section 14(3)(l) of the Regulation, the Project Proponent in the Project Plan
2119 are required to:

2120

2121 • Estimate the expected Project Reductions to be achieved by the Project during its
2122 Crediting Period.

2123 • Identify the basis on which the Project Emissions and Removals were estimated
2124 (14(3)(l)(i)).

2125 • Identify the formulas that will be used to determine the Project Reduction for each Project
2126 Report Period (14(3)(l)(ii)).

2127

2128 For each SSR identified in the Project Plan, Project Proponents must justify the calculation
2129 methodology used for the Project Crediting Period and why the activity levels that were estimated
2130 are reasonable.

2131

2132 In the Project Plan, the Project Proponent must present these estimates of future Project
2133 Reductions for each Project Report Period for the for the entire Project Crediting Period.

2134

DRAFT

2135

10.0 DATA COLLECTION AND MONITORING

2136

2137

In the Project Plan, the Project Proponents must detail their Monitoring and Maintenance plan in accordance with ISO 14064-2:2019 (sections 6.9 and 6.10), and record retention period established in the Regulation. The data collection and monitoring approach must be validated and followed throughout the Crediting Period and Monitoring Period.

2141

2142

For PoA Projects, some of the data or parameters may only available for aspects of the Project included at initial Validation. Project Instances added afterwards would be evaluated during the next Verification.

2143

2144

2145

2146

10.1 MONITORING PERIOD

2147

The Regulation stipulates a 100 year Monitoring Period for Sequestration Projects.

2148

2149

Monitoring Reports are required from the Project within six months at periods following the last day of the Project Crediting Period in Section 3.3. The required schedule for Monitoring Reports is in Table 6.

2150

2151

2152

2153

Table 6: Post Project Crediting Period Monitoring Requirements

Years after last day of Project Crediting Period.
25
50
75
100

2154

2155

The Project Proponent must submit the Monitoring Report to a Verification Body for verification in accordance with the verification and Monitoring requirements of the Regulation. Reversals that occur after the Project Crediting Period are addressed in the same manner as during the Project Crediting Period.

2156

2157

2158

APPENDIX A: PARAMETER CONSTANTS USED IN EQUATIONS

Parameter	Description	Value	Units	Equations Used	Source and notes (if applicable)
GWP	The global warming potential specified by the B.C. government for each GHG.	N/A	tCO ₂ e	Various	Where applicable, GWP is derived from the National Inventory Report (NIR) or the Intergovernmental Panel on Climate Change (IPCC) latest assessment, whichever is more recent. Emissions factors can be found in the NIR unless stated otherwise.
MW_{CO_2}	Molecular weight of CO ₂ .	44	g/mole	Equation 4 Equation 8 Equation 27	
MW_C	Molecular weight of carbon.	12	g/mole	Equation 4 Equation 8 Equation 27	
$HWPfact_{NA}$	The factor, derived from Table 2, for the proportion of CO ₂ remaining after the number of years between harvest and the Project Report Period, for products used in North America (NA). Measured as a proportion.	N/A	Measured as a percentage.	Equation 7	Derived from Table 2: Fraction of typical BC product mix remaining in-use.
$HWPfact_O$	The factor, derived from Table 2, for the proportion of CO ₂ remaining after the number of years between harvest and the Project Report Period, for products used offshore O. Measured as a proportion.	N/A	Measured as a percentage.	Equation 7	Derived from Table 2: Fraction of typical BC product mix remaining in-use.
$f_{C, wood}$	Fraction of the dry mass of wood, excluding bark that is carbon.	50%	Mass fraction	Equation 8 Equation 27	Petterson, R.C. (1984). The Chemical Composition of Wood. In R. Rowell (Ed.)

Parameter	Description	Value	Units	Equations Used	Source and notes (if applicable)
					<i>The Chemistry of Solid Wood</i> , (pp. 57-126). Advances in Chemistry. DOI:10.1021/ba-1984-0207.ch002
$vol_{s,d}$	Volume of delivered roundwood in m ³ of species <i>s</i> for each wood product destination <i>d</i> , extracted from the Project Site in each Project Report Period.	N/A	m ³	Equation 9	Based on sales invoices.
wdf_s	Wood density factor for species <i>s</i> , from Table 3. Measured in t/m ³ .	N/A	t/m ³	Equation 9	Values after Gonzalez, J.S. (1990). <i>Wood density of Canadian tree species</i> . (Information Report (Northern Forestry Centre (Canada)); NOR-X-315).mThe trees known in BC as “balsam” are true firs. Spruce includes Engelmann Spruce, White Spruce, and Hybrid Spruce. Determined in Table 3: BC-specific wood density factors (wdfs) for oven-dry stemwood to convert from inside-bark harvested volume (m3) to mass.
EF_f	Emission factor for GHG and fertilizer type <i>f</i> .	Dolomite (CO ₂): 0.13 Limestone (CO ₂): 0.12 Urea (CO ₂): 0.2 Ammonia (CO ₂): 671 Ammonia (natural gas)	kg C/ kg kg C/ kg kg C/ kg M ³ /tNH ₃ kg CO ₂ /m ³	Equation 10	2006 IPCC Guidelines, Vol. 4, Ch. 11. Table 11.1. Or, if applicable, in order of preference: 1. B.C. Reporting Regulation 2. Latest version of the B.C. GHG Inventory Report 3. Latest version of Canada's National GHG Inventory Report 4. Other recognized, justified reference Sources, with a preference for B.C.-specific data over national or international level data.

APPENDIX C: PROJECT-SPECIFIC EXTERNAL HARVEST-SHIFTING LEAKAGE DETERMINATION

2196 If a Project Proponent chooses not to select the provincial default values to calculate external
2197 Harvest-shifting Leakage, they may use Equation 29 to determine that rate.

2198
2199 The Project Proponent must assert in the Project Plan that Project-specific Leakage rates are
2200 representative of the Project and include justification for this assertion.

2201
2202
2203

Equation 29: % Leakage from external Harvest-Shifting

2204
$$\%Leakage_{External\ Harvest\ Shifting} = \frac{(100 * e * \gamma * C_N)}{([e - E * (1 + \gamma * \Phi)] * C_R)}$$

2205
2206

Where,

Parameter	Description	Default Value
$\%Leakage_{ExternalHarvest-shifting}$ <i>(shortened as %Leakage in Appendix B)</i>	Total increase in Project Emissions due to external Harvest-shifting Leakage during each Project Report Period, expressed as a percentage of the net Removals that is expected to shift to lands outside the ownership or control of the Project Proponent over the Project Report Period.	
e	Supply price elasticity.	See Below
E	Demand price elasticity.	
C_N	Carbon sequestration Reversal per unit of harvest from the non-reserved forest.	
C_R	Carbon sequestration per unit of (forgone) harvest gained by preserving the reserved forest.	
Φ	The “preservation” parameter. This is the ratio of timber supply being set aside for the Project (quantity Q_R) to the timber supply outside the offset area (quantity Q_N). The ratio can be represented as $\frac{Q_R}{Q_N}$ and can be thought of as the market share of the timber in the Project.	
γ	The “substitution” parameter. A parameter introduced into the referenced Leakage equation to take into account specialty woods (i.e. the degree to which a particular HWP can be substituted for another).	

2207
2208 The Project Proponent may use the variables that are used in the *Provincial Default Approach for*
2209 *Estimating Leakage* provided in Appendix C for supply price elasticity (E), demand price elasticity
2210 (E), and the carbon sequestration values (C_N and C_R) as identified in Table 7.

2211
2212
2213
2214
2215
2216
2217

2218 **Table 7: Default values for estimating Project-specific leakage**
 2219

Variable description	Default Equation Values (Interior)	Default Equation Values (Coast)
Supply price elasticity.	$e = 0.31$	$e = 0.66$
Demand price elasticity	$E = -0.12$	$E = -0.55$
Carbon sequestration Reversal per unit of harvest from the non-reserved forest.	$C_N = 1$	$C_N = 1$
Carbon sequestration per unit of (forgone) harvest gained by preserving the reserved forest.	$C_R = 1$	$C_R = 1$

2220
 2221 In order to tailor Leakage estimates to reflect a Project Specific Leakage case, it is recommended
 2222 that the Project Proponent focus on developing their own Project Specific parameters to reflect
 2223 the preservation parameter (Φ) and the substitutability parameter (γ).
 2224
 2225

2226 **Table 8: Variables recommended to be developed by the Project Proponent for estimating**
 2227 **Project Specific Leakage estimates**

Variable description	Equation Variable
<p>Substitution Parameter – A parameter introduced into the referenced Leakage equation to take into account specialty woods.</p> <p>Project Proponents who can demonstrate that specialty woods are prevalent in their Project Site develop the substitutability parameter using Equation 30. Otherwise, the default values provided in Table 7 must be used, reflecting the location of the Project.</p>	γ
<p>Preservation parameter – The ratio of timber supply being set aside for the Project to the timber supply outside the Project Site (the market share of the timber in the Project).</p>	Φ

2228
 2229
 2230 **Methodology for deriving a substitutability parameter (γ)**
 2231

2232 There are two key factors to consider when determining the substitutability parameter of a Project
 2233 1) tree species breakdown of the Project Site, and 2) cross-species product substitutability of
 2234 each given species, e.g., how many cedar products can be replaced with pine products?
 2235

2236 A Project Proponent must use a representative and validated sample of tree species harvest
 2237 makeup for their Project Site.
 2238
 2239
 2240

2241
 2242

2243

2244 **Equation 30: Weighted Substitution Parameter**

2245
$$\gamma = \sum_{s=1}^n T_s * S_s$$

2246 Where,
2247

Parameter	Description	Default Value
γ	The “substitution” parameter. A parameter introduced into the referenced Leakage equation to take into account specialty woods (i.e. the degree to which a particular HWP can be substituted for another).	
s	A specific tree type	N/A
n	Number of tree types within the Project	N/A
T_s	Tree type i 's share of Project's total marketable tree volume	N/A
S_s	Substitutability of tree type i	N/A

2248
2249 If a substitution parameter is determined for this representative sample, on average it is going to
2250 be accurate (representative) of a Project in this area, taking into account “specialty woods” that
2251 are more difficult to substitute, such as cedar or cypress. The contribution to total harvest of these
2252 specialty woods is combined with species-specific substitutability to create a weighted average
2253 for the substitutability parameter. The weighted average is then applied to the Leakage equation,
2254 reducing Leakage from a Project by the weighted average (represented as a percentage) of its
2255 original level.

2256
2257 **Methodology for deriving a preservation parameter (Φ)**

2258
2259 The preservation parameter (Φ) represents the ratio of timber set aside for the offset Project
2260 (quantity Q_R) to the timber supply outside the Project Site (quantity Q_N). The ratio can be
2261 represented as Φ and can be thought of as the market share of the timber in the Project.

2262
2263 Option 1: The Project Proponent may determine their own preservation parameter according to
2264 Equation 31.

2265
2266
2267 **Equation 31: Preservation parameter**

2268
$$\Phi = \frac{Q_R}{Q_N}$$

2269 Where,
2270

Parameter	Description	Default Value
Φ	The “preservation” parameter. This is the ratio of timber supply being set aside for the Project (quantity Q_R) to the timber supply outside the offset area (quantity Q_N). The ratio can be represented as Q_R/Q_N and can be thought of as the market share of the timber in the Project.	
Q_R	Quantity of harvestable timber (m^3) to be claimed during Project Report Period.	N/A
Q_N	Quantity of harvestable timber supply (m^3) remaining in the market.	N/A

2271 The remaining supply of timber (Q_N) will be the five year average annual total timber harvest in
 2272 North America for the most recent period.

2273
 2274 Option 2: The provincial default Leakage values use a 1% (.01) preservation parameter.
 2275

2276
 2277 **Additional requirements Project Specific Leakage**
 2278

2279 Where a Project-specific Leakage approach is taken for deriving any of the parameters in
 2280 Equation 29, the additional requirements detailed in
 2281 Table 9 must also be satisfied.
 2282

2283
 2284 **Table 9: Additional Requirements for using coefficients in the Leakage equation**

Supply (E) and Demand (E) Elasticities	<ul style="list-style-type: none"> • North American market data must be used when estimating elasticities for the purpose of determining Leakage from Projects in B.C. <ul style="list-style-type: none"> ○ The price elasticities of total demand and supply of BC logs should be used that incorporate the dynamics of domestic and significant international markets relative to BC (e.g. US, China, and Japan). Otherwise, relevant price elasticities of total demand and supply for BC lumber may be used with appropriate justification. ○ The uniqueness of B.C. forests, and therefore a B.C. based Project, will be captured by the substitution parameter. • Elasticity estimates used by a Project Proponent for both supply and demand must be derived from the same data sets and information/ study in order to ensure consistency in derivation and validate their application for estimating Project Leakage. • Both market supply and market demand elasticities used in the Protocol Leakage methodology must be long-run elasticity estimates.
Carbon sequestration values (C_N and C_R)	<ul style="list-style-type: none"> • Project Proponents choosing to develop their own Leakage value must use a value of 1 for C_N and C_R in the Leakage formula.
Preservation Parameter (Φ)	<ul style="list-style-type: none"> • Project Proponents that estimate this parameter must demonstrate the harvest potential (or forgone harvest since the last Project Report Period) that their respective Project has in terms of total North American timber sales over the previous year.
Substitutability Parameter (γ)	<ul style="list-style-type: none"> • The Project Proponent must follow the substitution guidelines when calculating their own substitution parameter (see Appendix E: Example Substitutability Equations). • Project Proponents must demonstrate the tree species contribution/makeup within their Project Site. • The Project Proponent must demonstrate the substitutability of tree species in terms of potential wood products. • The Project Proponent must apply long-run, own- and cross-price elasticities of demand for substitutable wood products in North American market to derive the substitutability parameters.

2285

2286

2287
2288

APPENDIX D: THE PROVINCIAL DEFAULT VALUES FOR ADDRESSING LEAKAGE FROM FOREST CARBON PROJECTS

2289 Growing conditions, the destinations of wood, and tree type vary considerably between the interior
2290 and coastal regions of B.C.. In addition, areas in the southern interior of B.C. can vary
2291 considerably from the northern interior. These differences impact the parameters of the Leakage
2292 equation (Appendix C, Equation 29) and as such we examine default values for the northern
2293 interior, southern interior and coastal regions separately.

2294
2295 Assumptions made for the default values of both the coast and northern and southern interior
2296 reflect what are simple and representative offset Projects in each respective region. Assumptions
2297 such as tree type, location, and product type can all impact the estimated Leakage. As a result
2298 these calculations could be modified on a Project to Project basis by the Project Proponent
2299 through using the Leakage equation guidelines in the Protocol and by referring to the default
2300 Scenarios.

2301
2302 A Project timeline of 100 years to be consistent with monitoring provisions in the Regulation. To
2303 reflect this long-run market elasticities are used instead of short-run elasticities. The market share
2304 of the default offset Project is assumed to be 1% ($\Phi = .01$) of the total North America market. CR
2305 and CN are assumed to be the same and are given values of 1 as a conservative assumption to
2306 lower the chance of underestimating Leakage.

2307
2308
2309 **Table 10: Leakage Estimate and Parameters Using the Price Elasticities of Total Supply**
2310 **and Demand of BC Logs**

	Total Supply Price Elasticity (E)	Total Demand Price Elasticity (E)	Preservation Parameter (ϕ)	Carbon Sequestration Reversal from Non-reserved Forest (CN)	Carbon Sequestration gained from the reserved Forest (CR)	Substitution (γ)	%Leakage
Northern Interior	0.31	-0.12	0.01	1	1	1.0000	71.89
Southern Interior	0.31	-0.12	0.01	1	1	0.9622	69.18
Coast	0.66	-0.55	0.01	1	1	0.8719	47.37

2311
2312
2313 **3. Northern Interior B.C. Default Values:**
2314

2315 In this guideline, the northern interior region of B.C. is generally referred to as the northern part
2316 of the province that contains pine and spruce trees as the dominant leading species. Although
2317 the majority of BC lumber products are exported to the US, domestic and other significant
2318 international export markets need to be considered to reflect a more complete and accurate
2319 picture of market conditions when determining default Leakage parameters. Specifically, we
2320 examine the Canadian export market to the US, China, and Japan. Therefore, supply and demand
2321 elasticities of BC logs in both domestic and the three predominant international markets

2322 mentioned are used. Default Leakage values are estimated via using export supply price elasticity
2323 (E) of 0.31, and a demand price elasticity (E) of -0.12 (Latta and Adams, 2000). From this, the
2324 provincial default estimate of Leakage for the Northern Interior is 71.9%, as seen in Table 11
2325 below.

2326
2327

2328 **Table 11: Northern Interior Leakage Estimation**

$e = 0.31$
$E = -0.12$
$C_R = 1$
$C_N = 1$
$\Phi = .01$
$\gamma = 1$
L = 71.9%

2329
2330 For the northern interior default values, it is assumed that the wood supplied from this geographic
2331 area can be substituted with any number of other wood alternatives (harvested in B.C. or
2332 elsewhere) to generate the same product lines. Tree species that have a high number of
2333 alternative species, in terms of the product lines they are geared for are referred to as highly
2334 substitutable. This is generally the case for species such as pine and spruce which are the leading
2335 commercial timber species in the northern interior.

2336
2337 There may be instances where the Project Proponent have other species of commercially
2338 harvestable timber within their Project Site. If the Project Proponent can demonstrate that these
2339 commercial tree species have low or moderate substitutability, it is recommended that the Project
2340 Proponent utilize the methodology applied in the coastal and southern interior default values to
2341 refine/ tailor the northern interior default values to reflect their specific Project dynamics.

2342
2343 **4. Coastal B.C. Default Values:**

2344
2345 This default value represents an offset Project in coastal B.C. instead of in the northern interior.
2346 Good growing conditions for trees on the coast, allowing trees to become larger more quickly than
2347 other areas of the province, make coastal areas desirable for offset Projects.

2348
2349 Supply and demand elasticities for coastal logs are comparatively higher than the interior (Sun et
2350 al. (2015), Latta & Adams, 2000). For regions that grow certain woods that have few substitutes
2351 for their product lines, such as cedar on the coast, Leakage is likely lower. This is simply due to
2352 the fact that the constrained supply is not replaced, or less easily replaced by the supply of another
2353 wood species. There is a supply constraint and less likelihood of Harvest-Shifting relieving that
2354 constraint. Therefore coastal Projects (or Projects in areas containing woods with low
2355 substitutability) warrant lower Leakages.

2356
2357 Applying the substitutability parameter to reflect low substitutability woods on the coast indicates
2358 the Leakage estimate is reduced to 47.4% for the coastal default value as indicated in Table 12
2359 below. It is important to note that the default value for the coast represents the average mix of

2360 tree species in the total harvest area of the coastal region. Leakage estimates for Projects on the
 2361 coast can vary according to species composition and the proportion of low substitutability species
 2362 to high substitutable species in the Project Site. An example calculation result of 54.3% Leakage
 2363 is also shown in Table 13 below if we assumed perfect substitutability of species on the coast:

2364
 2365
 2366

Table 12: Coastal Leakage Estimation

Perfect Substitutes	Moderate Substitutes
$e = 0.66$	
$E = -0.55$	
$C_R = 1$	
$C_N = 1$	
$\Phi = .01$	
$\gamma = 1$	$\gamma = .8719$
%Leakage = 54.3%	%Leakage = 47.4%
$e = .342$	
$E = -.181$	
$C_R = 1$	
$C_N = 1$	
$\Phi = .01$	
$\gamma = 1$	$\gamma = .8479$
%Leakage = 65%	%Leakage = 55.3%

2367
 2368 For the coastal default value, the average tree species mix for the entire coastal harvest region
 2369 was used. To derive a substitutability parameter (γ) for a specific Project, a Project Proponent
 2370 needs to ascertain the representative tree species mix for their specific Project Site (in place of
 2371 the average tree species mix for the coastal harvest area). For the coastal default value, red
 2372 cedar and cypress are identified as low substitutability woods, white pine is identified as
 2373 moderately substitutable. All other commercially harvested trees in the coastal region are
 2374 assumed to be perfectly substitutable (100% substitutability).

2375
 2376 A total of 21.28% of wood (cedar and cypress) has 40% substitutability. White Pine, making up
 2377 0.12%, is 70% substitutable. The remaining 78.59% of the wood is 100% substitutable, this means
 2378 that all products from a tree in this category can be replaced by the same or similar products of
 2379 other trees.

2380
 2381 This weight is then applied to the Leakage equation, reducing Leakage from the 'perfectly
 2382 substitutable' default value (the northern interior default value) to approximately 87% of its original
 2383 level and is now representative of the total average coastal market. See Table 14 and associated
 2384 calculation below.

2385 **Table 13: Low and moderately substitutability wood as a contribution of total coastal**
 2386 **harvest**

	Cedar	Cypress	White Pine	Other	Total
Harvest Contribution (T)	18.71%	2.57%	0.12%	78.59%	100.00%
Substitution (S)	40%	40%	70%	100%	87.19%

2387
 2388 **Coastal Substitution Calculation:**

2389
 2390 $\gamma_{Coast} = T_{cedar} * S_{cedar} + T_{cypress} * S_{cypress} + T_{white\ pine} * S_{white\ pine} + T_{other} * S_{other}$

2391
 2392 $\gamma_{Coast} = .1871 * .4 + .0257 * .4 + .0012 * .7 + .7859 * 1 = .8719$

2393
 2394
 2395 **5. Southern Interior B.C. Default Value:**

2396
 2397 The southern interior default value represents the general geographic extent of cedar trees (a low
 2398 substitutability wood) in the interior of B.C.. The southern interior of B.C. has a diversity of tree
 2399 species and growing sites. Project Sites can be highly variable and it may be appropriate to derive
 2400 a substitution parameter specific to individual Projects.

2401
 2402 The methodology for estimating Leakage for the southern interior default value follows that of the
 2403 coastal default value. In this default value, a substitutability parameter is derived to reflect the
 2404 average tree species mix for the total southern interior harvest region.

2405
 2406
 2407 **Table 14: Low and moderately substitutable wood as contribution of total southern interior**
 2408 **harvest**

	Cedar	Larch, Yellow & White Pine	Other	Total
Harvest Contribution	4.63%	3.34%	92.03%	100%
Substitution	40%	70%	100%	96.22%

2409
 2410
 2411 **Southern Interior Substitution Calculation:**

2412
 2413 $\gamma_{South} = T_{cedar} * S_{cedar} + T_{larch} * S_{larch} + T_{other} * S_{other}$

2414
 2415 $\gamma_{South} = .0463 * .4 + .0334 * .7 + .9203 * 1 = .9622$

2416
 2417
 2418 Although the southern interior uses the same supply and demand elasticities as the northern
 2419 interior and there is a higher substitutability of species than on the coast, it is not perfect
 2420 substitutability. Therefore, the default Leakage estimate for the south interior is slightly lower at
 2421 69.2% when compared to the northern interior. See Table 16 below:

2424 **Table 15: Southern Interior Leakage Estimation**

$e = 0.31$
$E = -0.12$
$C_R = 1$
$C_N = 1$
$\Phi = .01$
$\gamma = 0.9622$
$L = 69.2\%$

2425
2426 As with the coastal case, to derive a substitutability parameter (γ) for a specific Project in the
2427 southern interior, a Project Proponent needs to ascertain the representative tree species mix for
2428 their specific Project Site and reflect that in the calculation with the respective substitutability of
2429 those tree species.

2430
2431

DRAFT

2432

APPENDIX E: EXAMPLE SUBSTITUTABILITY EQUATIONS

2433 The substitution parameter measures the rate of response of quantity demanded of product N
 2434 due to the quantity change of product R . Hence, in order to get the substitution parameter from
 2435 cross price elasticity, the following calculation is applied:

2436

2437 Substitution parameter = cross price elasticity for product R^* inverse of own price elasticity of
 2438 product R

2439

$$2440 \quad S = \frac{dq_N/q_N}{dq_R/q_R} = \frac{dq_N/q_N}{dp_R/p_R} * \frac{dp_R/p_R}{dq_R/q_R}$$

2441

2442 The substitutabilities of low/ moderately substitutable wood (imperfect substitutes) in this paper
 2443 are determined base on the references listed below.

2444

	(0.76)	(0.07)	(0.45)	(0.07)	(0.09)	(0.06)	(0.05)	(0.20)

NOTE: Numbers in parentheses are approximate standard errors that ignore possible correlation between the import shares and elasticities in the equations provided. Elasticity values indicate the price of imports of various species.
 *Significantly different from zero at the 5% significance level using a two-tailed test.

2452 Source: Hseu and Buongiorno (1993)

2453
 2454 Only substitutable woods with the price elasticities that are higher than 5% significance level are
 2455 considered in calculating the substitution parameters. For example, to calculate the substitution
 2456 parameter for red cedar:
 2457

2458
$$S_{red\ cedar} = \frac{E_{pine}}{E_{red\ cedar}} + \frac{E_{hemlock}}{E_{red\ cedar}} = \frac{.29}{-1.03} + \frac{.12}{-1.03} = -40\%$$

2459
 2460 To calculate the substitution parameter for larch, the table from Nagubadi *et al.* (2004) is used:
 2461

2462
$$S_{larch} = \frac{E_{wsp}}{E_{other}} = \frac{.3014}{-.4275} = -70\%$$

2463
 2464 Note that the price elasticities of larch, ponderosa pine, redwood, white pine and other lumber
 2465 were grouped together in the "Other" group in this reference.

APPENDIX H: RISK OF REVERSAL DETERMINATION

2492

Determining the Risk of Reversal

2493

2494 Contributions to the Contingency Account will be determined by natural disturbance type, and is
2495 equal to the percentage likelihood of non-survival, as represented by Equation 32.

2496

2497

2498

Equation 32: Percentage of units contributed to the Contingency Account

2499

$$\beta = 1 - P^Y - RMM$$

2500

2501

Where,

Parameter	Description	Default Value
β	Percentage of units contributed to the Contingency Account at each Project Issuance	N/A
P^Y	Chance of surviving up to t years without a disturbance. Determined with Equation 33.	N/A
RMM	Risk Mitigation Measures. See below.	N/A

2502

2503

2504

Equation 33: Chance of surviving up to t years without a disturbance

2505

$$P^Y = \exp\left(\frac{-Y}{DRI}\right)$$

2506

2507

Where,

Parameter	Description	Default Value
P^Y	Chance of surviving up to Y years without a disturbance, DRI. This is the negative exponential version of equation 6.3 on page 81 of Johnson, EA 1992. Fire and Vegetation Dynamics (Cambridge University Press).	N/A
Y	Number of years starting at the Project inception and continuing 100 years past the termination of the Crediting Period.	125 years
DRI	Mean disturbance return interval based on natural disturbance type, found in Table 20. Mean disturbance intervals are from Government of British Columbia (1995). Biodiversity Guidebook (Province of British Columbia, Victoria, Canada, 110 pp.).	See Table 20

2513

2514

2515 **Table 20: Mean disturbance return interval**

Natural disturbance type	Mean disturbance return interval (DRI)
1: Ecosystems with rare stand-initiating events	250 years for the CWH and ICH,
	350 years for the ESSF and MH
2 – Ecosystems with infrequent stand-initiating events	200 years
3 – Ecosystems with frequent stand-initiating events	100 years for wind-dominated CWH and SBPS and BWBS with deciduous species prominent.
	125 years for the SBS and BWBS with coniferous species prominent.
	150 years for ESSF, ICH and MS units
4 – Ecosystems with frequent stand-maintaining fires	150 to 250 for the IDF (stand replacing)
5 – Alpine Tundra and Subalpine Parkland ecosystems	Not clear in part because open, woodland type ecosystems, may not fit definition of forest.

2516

2518
2519
2520
2521

Table 21 summarizes the chance of survival and corresponding Contingency Account contribution rates:

Table 21: Chance of survival and corresponding Contingency Account contribution rates

Natural disturbance type	Mean disturbance return interval (DRI)	Chance of surviving up to 25 years	Chance of surviving up to 125 years	Risk of Reversal
1: Ecosystems with rare stand-initiating events	250 years for the CWH and ICH,	0.90	0.61	0.39
	350 years for the ESSF and MH	0.93	0.70	0.30
2 – Ecosystems with infrequent stand-initiating events	200 years	0.88	0.53	0.46
3 – Ecosystems with frequent stand-initiating events	100 years for wind-dominated CWH and SBPS and BWBS with deciduous species prominent.	0.78	0.29	0.71
	125 years for the SBS and BWBS with coniferous species prominent.	0.82	0.37	0.63
	150 years for ESSF, ICH and MS units	0.85	0.43	0.56
4 – Ecosystems with frequent stand-maintaining fires	150 to 250 for the IDF (stand replacing)	0.85 to 0.90	0.43 – 0.61 (average is 0.52)	0.48
5 – Alpine Tundra and Subalpine Parkland ecosystems	Not clear in part because open, woodland type ecosystems, may not fit definition of forest.			

2522 **Determining Risk Mitigation Measures**

2523

2524 Deductions to the Risk of Reversal may be applied based on mitigating factors specific to the
2525 Project. For each Risk Mitigation Measure, Proponents will be required to identify what natural
2526 disturbance that Risk Mitigation Measure is addressing, in addition to the likelihood and
2527 magnitude of risk mitigated through each measure. Assumptions used to inform the Risk
2528 Mitigation Measure selection must use peer-reviewed research, government publications (from
2529 the Government of Canada or Government of B.C.), or data from within 10 years.

2530

2531 Risk Mitigation Measures may include (but are not limited to):

2532

- The Project takes place within a FireSmart area,
- An annual Fire Plan in place for the Project Site,
- Fire line construction within the Project Site,
- Initial fire suppression equipment on or adjacent to the Project Site,
- Regular low intensity burning used to control fuel load,
- Diversity of tree species within the Project Site,
- Relevant improved (i.e. drought resistant) tree genotypes used within the Project Site,
- Road accessibility,
- Use of remote sensing,
- Moisture regime of Project Site,
- Slope of stands within the Project Site are less than 10%,
- The Project Site is more than 5 kilometers from a railroad, and
- Decreased risk to the Project due to Project type.
