Re: Status Update for Fraser River Late-Run Summer Steelhead

Fraser River Late-run summer steelhead is a group of 10 spatially discrete spawning stocks distributed in the Fraser watershed upstream of Hell's Gate. Four of these stocks spawn in the Thompson watershed, two spawn in the Chilcotin watershed, and the remaining four spawn in other watersheds that are tributaries to the middle reaches of the Fraser River.

The current spawning population forecast for the **Thompson** watershed is **536** (95% credible interval 283-1103). Currently, the probability that Thompson steelhead will be classified as an **Extreme Conservation Concern** is **22%**, the probability that they will be classified as a **Conservation Concern** is **76%**, and the probability that they will be classified as **Routine Management** abundance is **2%**. Reference points for the Thompson watershed that define conservation classifications are the Limit Reference Point of 431 and the Conservation Concern Threshold of 1187. Below 431, Thompson steelhead are classified as an Extreme Conservation Concern. Between 431 and 1187, Thompson steelhead are classified as a Conservation Concern.

The current spawning population forecast for the **Chilcotin** watershed is **198** (95% credible interval 113-636). The current probability that Chilcotin steelhead will be classified as an **Extreme Conservation Concern** is **68%**, the probability that they will be classified as a **Conservation Concern** is **31%**, and the probability that they will be

classified as **Routine Management** abundance is **1%**. Reference points for the Chilcotin steelhead that define conservation classifications are the Limit Reference Point of 296 and the Conservation Concern Threshold of 763. Below 296, the Chilcotin steelhead are classified as an Extreme Conservation Concern. Between 296 and 763, the Chilcotin steelhead are classified as a Conservation Concern.

Conservation classifications are described further in the Provincial Framework for Steelhead Management in BC (2016) and supporting technical documents.

The current forecasted spawner abundance for the Thompson ranks 38th over a 48-year monitoring time frame. The current forecast for the Chilcotin ranks 43rd over a 54-year monitoring time frame.

The run of Thompson, Chilcotin, and other Fraser River late-run summer steelhead stocks occurs over about a 12-week period and normally peaks in the Johnstone Straits and in Juan de Fuca Strait in late September. In the lower Fraser test fishing areas near Fort Langley, the run normally begins in late August and continues into the latter half of November, peaking in early-to-mid October. Stocks that spawn furthest inland (i.e. Chilcotin watershed) tend to arrive earliest while stocks that spawn furthest downstream (i.e. Nahatlatch) tend to arrive latest. The remaining stocks which include those that spawn in the Bridge, Seton, Stein, and in the tributaries of the Thompson watershed (i.e. Deadman, Bonaparte and Nicola watersheds), tend to be intermediate in their arrival timing to the Fraser River.

This is the last report on the status of Fraser River Late-Run Summer Steelhead for the fall migration period in 2024. These steelhead will overwinter in the Thompson, Chilcotin and Fraser rivers and then complete their upstream migration into spawning tributaries in the spring. An update will be provided in the summer of 2025 following the completion of population abundance assessments in the spawning areas.
