

# Okanagan Lake (South) Phytoplankton Summary Report 2021-2022

## Overview

Samples were collected from EMS site #0500454 on Okanagan Lake during 2021 and 2022 (Figure 1; Table 1). Algae were identified to the taxonomic level of species and grouped into broad alga types for analysis.

Table 1: Sample sites and dates sampled in 2021 and 2022

Sample Site (EMS#)	Dates

	2022-08-16
	2022-09-07

**Total= 11 samples**

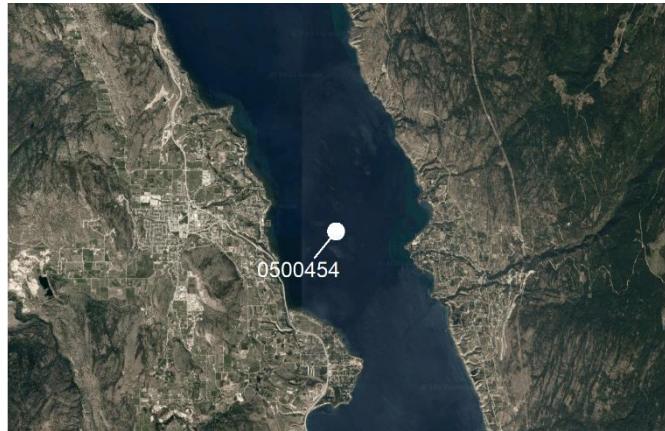

Figure 1: Aerial view of EMS site 0500454 Okanagan Lake

Samples demonstrated seasonal patterns with elevated diatoms in the spring. Diatom concentrations were slightly elevated from April to June compared to March, July, August, and September. Spring blooms of diatoms are common and reflective of increased temperatures, light penetration, and silica in the water following ice thaw (Kong et al., 2021). EMS site 0500454 collected on 2022-03-07 demonstrated diatom degradation indicative of lowering silica levels in the late spring (Figure 2).

Samples collected at EMS site 0500454 demonstrated elevated concentrations of cyanobacteria compared to Northern sample points in Okanagan Lake (EMS 0500730 and 0500236).

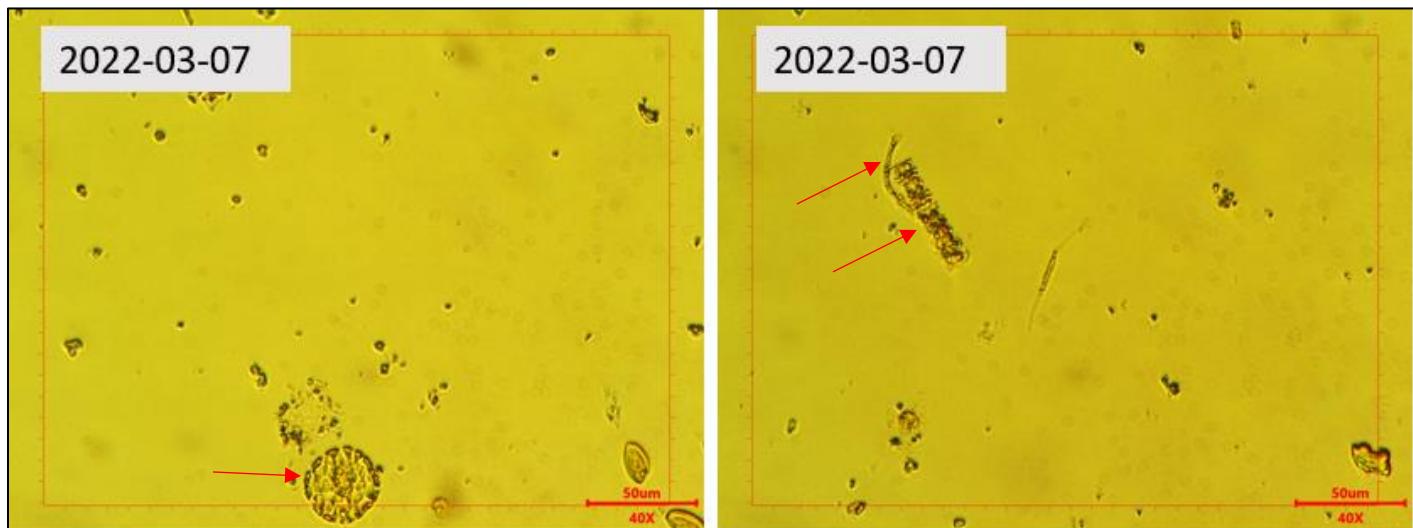

Figure 2: 400x magnification of EMS site 0500454 collected on 2022-03-07 highlighting the degraded diatoms (red arrows) observed in this sample

## Overview (continued)

Diatoms dominated biovolumes in Okanagan Lake (South), over 42% of sample biovolume was composed of diatoms (Figure 3; Figure 4). Cryptomonas species were also frequently encountered.

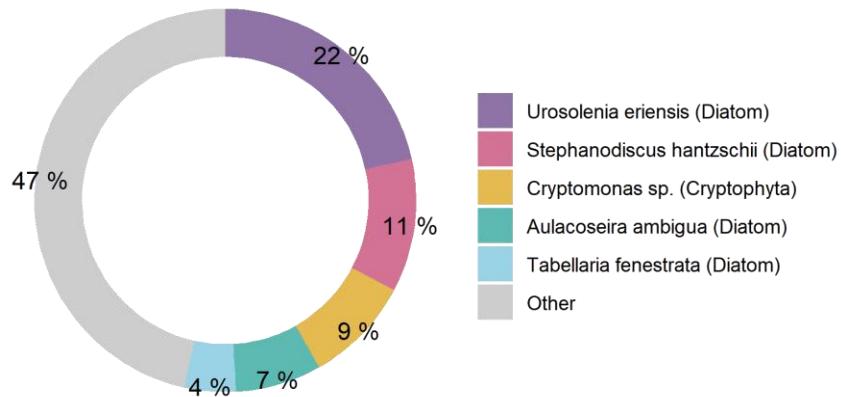

Figure 3: Dominant organisms from Okanagan Lake (Site 0500454) as percent of total biovolume

Diatoms are integral to aquatic food webs because they are the foundation of the food web (jrobyn, 2019). Colony forming diatoms such as *Fragilaria* and *Tabellaria* sp. can avoid grazing pressures by developing into large colonies reducing their availability for zooplankton and microscopic invertebrates (Baker, 2012).

Cryptomonads are favored elements of freshwater food chains and are selectively consumed by several zooplankton, ciliates, and dinoflagellates (Wehr et al., 2015).

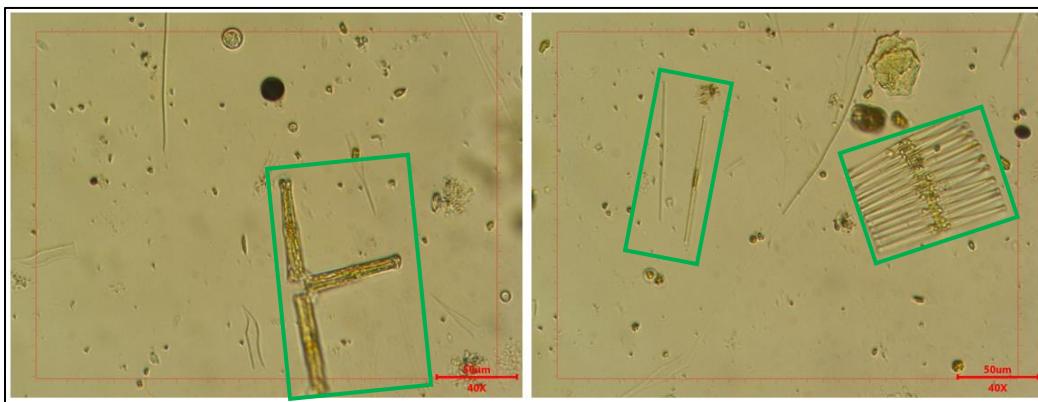

Figure 4: 400x magnification of EMS site 0500454 demonstrating the size of different diatoms (green boxes)

Algae – why should we care?

Algae blooms are becoming more frequent and severe worldwide due to excessive nutrient loading and warming summer lake temperatures. Diatom blooms can cause filter clogging, and odor issues.

Intense cyanobacteria blooms can threaten human safety and aquatic health through their toxicity. Illness related to cyanotoxins can include liver, kidney, and nerve cell damage, cancer, skin and gut irritation, and neurological issues. Cyanotoxins, including microcystins, are now known to accumulate in the food chain (Lance et al., 2014). Fish from lakes with heavy cyanobacteria blooms can have higher toxin concentrations than the lake water (Greer et al. 2021) and consuming them can increase the risk of liver disease (Zhao et al., 2020).

## Cyanobacterial Presence

Samples collected during June 2021 and 2022 contained elevated counts of cyanobacteria. *Planktolyngbya* was the dominant genus counted, *Anacystis* and *Aphanocapsa* were also frequently encountered.

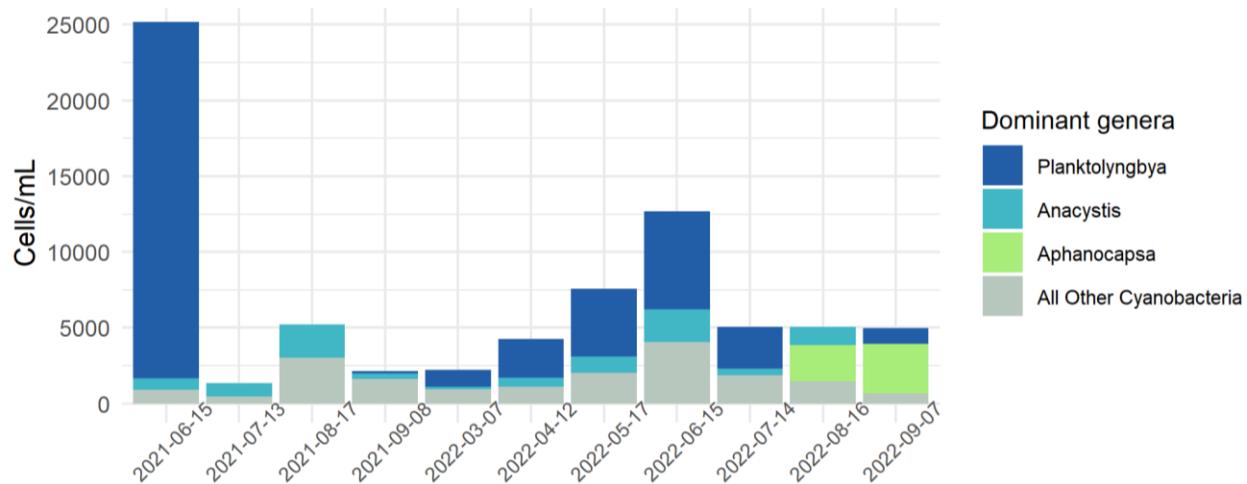

Figure 5: cell abundance for dominant cyanobacteria genera on Okanagan Lake (South)

Dominant cyanobacteria identified in the summer samples are also associated with several cyanotoxins that represent risks to public health (Table 2). Illness related to cyanotoxins can include liver, kidney, and nerve cell damage, cancer, skin and gut irritation, and neurological issues (Lance et al., 2014).

Table 2: Dominant genera of cyanobacteria on Okanagan Lake (South) and their associated toxins

Genus	Maximum Abundance* (cells/mL)	Toxins Produced
<b>Planktolyngbya</b>	20036	Lyngbyatoxin LYN, Microcystin MC, BMAA
<b>Aphanocapsa</b>	3263	Lyngbyatoxin LYN, Lipopolysaccharide LPS, Microcystin MC, BMAA
<b>Anacystis</b>	1821	Lyngbyatoxin LYN, Lipopolysaccharide LPS, Microcystin MC, Nodularins NOD, Anatoxins (-a) ATX, BMAA, Cyanopeptolins CPL, Anabaenopeptins APT

Note: \* = counted in samples

## Cyanobacterial Presence (Continued)

Dominant species of cyanobacteria found in Okanagan Lake (South) can produce cyanotoxins (Table 2).

Okanagan Lake (South) displayed cyanobacteria levels in the negligible to moderate-risk category, with a mean cyanobacteria abundance of 6,887 cells/mL (Figure 6). Figure 6 exhibits the range of cyanobacterial abundance observed in Okanagan Lake (South) compared to alert levels defined by several authorities including the WHO and EPA.

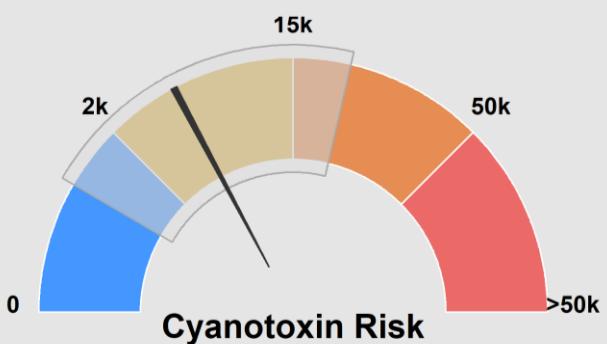

Figure 6: Cyanotoxin risk posed by cyanobacteria blooms in Okanagan Lake (South)

Cyanobacteria frequently dominate algal communities in total cell count, but because of their small cell size their biovolume is usually low relative to the other types of algae present. This is highlighted in Figure 7 where a half of an *Ulnaria ulna* cell (diatom) is an equivalent length to approximately 100 cyanobacteria cell on an adjacent filament.

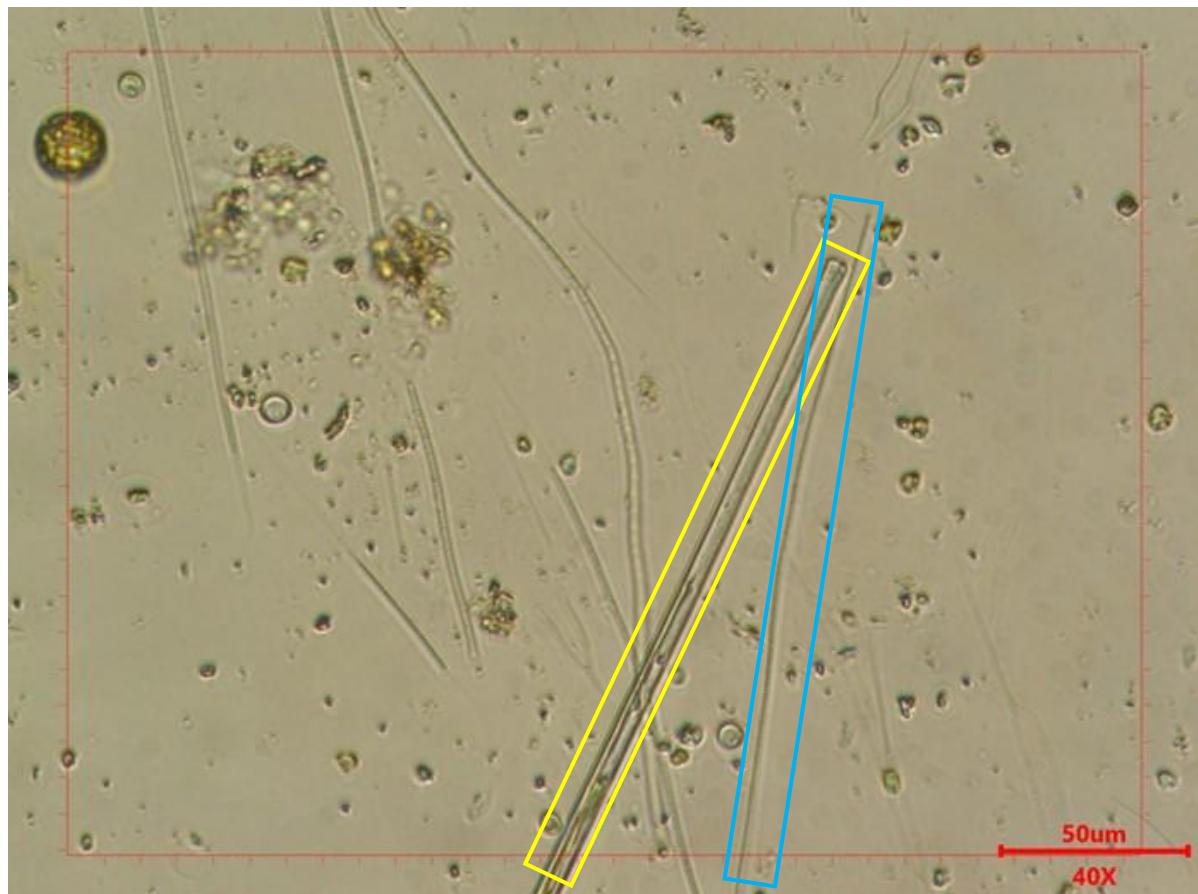

Figure 7: Size comparison of a half *Ulnaria ulna* cell (yellow box) to a filament of *Planktolyngbya* (blue box) approximately 100 long

## Species Composition

Algae samples were identified to the species level and grouped into broad alga types for analysis. The figures below display the total cell counts for each broad algae group alongside the biovolume represented by each of these groups. The difference between Figure 8 (cell abundance) and Figure 9 (biovolume) illuminates the difference between cell abundance and biovolume.

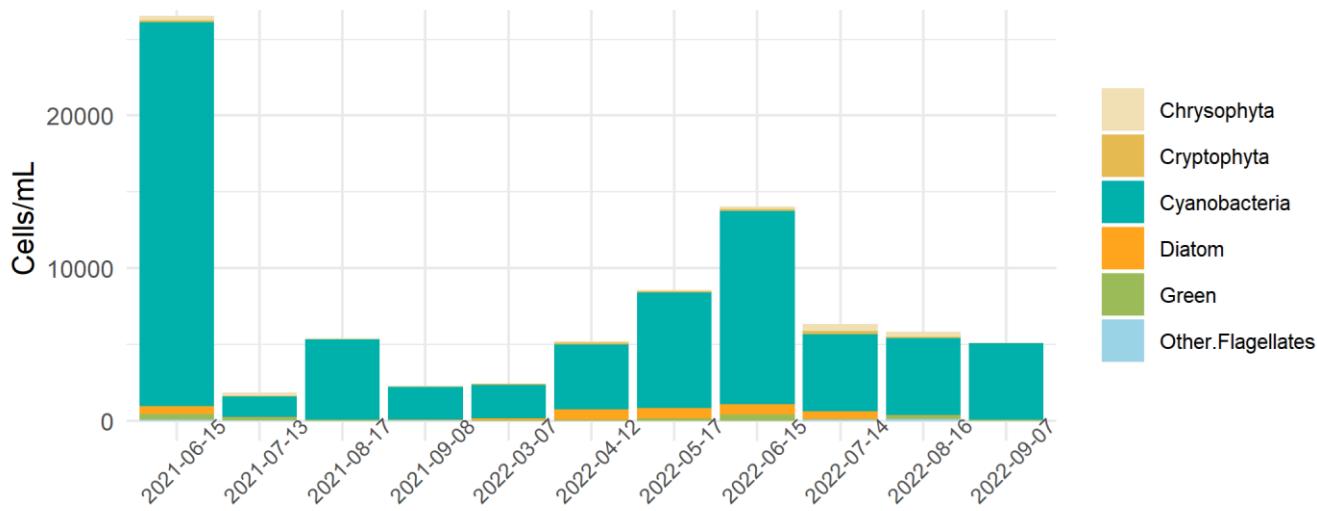

Figure 8: Cell abundance of high-level taxa groups on Okanagan Lake (South)

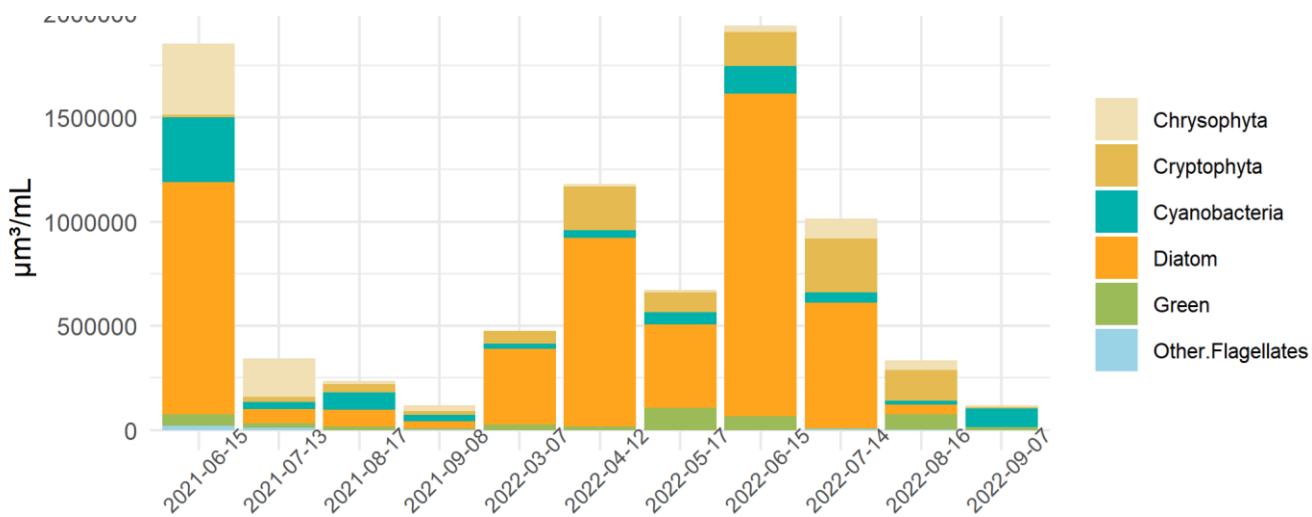

Figure 9: Biovolume of high-level taxa groups on Okanagan Lake (South)
