## ACKNOWLEDGEMENTS

### Land Acknowledgement

The Ministry of Agriculture and Food acknowledges the territories of First Nations around B.C. and is grateful to carry out our work on these lands.

### Contributors

Thank you to the producers and industry representatives who participated in our Regional Extension Committee. The time and expertise committed to this work was indispensable.

### Credits

Content prepared by **the B.C. Agriculture Climate Action Research Network**.  
Graphic design by **VGN Resources Group**  
Front cover photos: Top: B.C.Photo; Bottom: Brenna Schilds  
Back cover photos - from top: Emrys Miller; Ministry of Agriculture and Food; Brenna Schilds; Tanner Yould/Unsplash

### Funding

Financial support was provided under the Sustainable Canadian Agricultural Partnership, a federal-provincial-territorial initiative. Additional funding has been provided by CleanBC.

# Introduction to the guide

Agricultural producers are grappling with the impacts of climate change and are on the front lines of developing strategies that maintain economic viability alongside environmental sustainability. Top issues, response strategies, and feasibility of practices differ across British Columbia's diverse ecoregions, highlighting the need for targeted extension and applied research projects. To meet these needs, the B.C. Ministry of Agriculture and Food's new Regional Extension Program aims to increase on-farm adoption of management practices that support producers in making their operations more climate resilient, sustainable, and economically viable.

This regional guide aims to serve as a resource for producers, on-the ground researchers, and consultants to reflect on the climate issues challenging environmental sustainability and local farm businesses and food production.

In this guide, three overarching strategies address the agricultural climate and environment priorities identified by producers across the province:

**Adaptation:** Prepare for and respond to a changing climate. Practices in this guide are largely adaptation focused, reflecting the immediate impacts producers are experiencing.

**Mitigation:** Reduce greenhouse gas emissions and increase carbon sequestration.

**Environment:** Protect and regenerate soil, water, and air quality. Improve biodiversity and protect sensitive habitats.

The priority issues highlighted in this guide were identified by a regional extension committee that represents the climates, soils, and commodity groups in each region, facilitated by the B.C. Ministry of Agriculture and Food. For more information, contact your Regional Agrologist or [AgriServiceBC](#). The content of this document may change with the results of engagement with producers in the region.

Each priority issue described in this guide includes:

- ▶ **An overview of the priority** and why it is important to producers in the region.
- ▶ An **inventory** of past and current applied research and extension projects relevant to the issue. Many of these projects were implemented under the BC Ministry of Agriculture and Food's Climate Change Adaptation Program (2008-2023) with support from government, industry, and research partners.
- ▶ **Beneficial management practices and work that can be built on** to address priority areas.
- ▶ Current **funding programs** associated with each priority area.
- ▶ Current **provincial tools** relevant to each priority area.

# Introduction to the region

## Regional boundaries

For the purpose of the Regional Extension Program, the Highway 16 and North Cariboo agricultural extension region comprises the Cariboo Electoral Areas A, B, C, and I, and the Bulkley-Nechako, Fraser-Fort George, Kitimat-Stikine, and North Coast regional districts. This region includes portions of the Cariboo, Nechako, and North Coast agricultural census districts. The statistics included throughout this document reference the regions that are used to collect the associated data and may not reflect the regional boundaries for this program.

# Agricultural Sector Demographics

## Mixed Livestock

Photo: Nicole Pressey

### TRENDS IN FARM NUMBERS, FARM TYPE, AND FARMLAND AREA

*(Census of Agriculture, 2021)*

- ▶ In the Nechako, farm numbers decreased by 12% and farmland area decreased by 14.5% between 2011 and 2021. Hay production has decreased the most – the number of farms producing hay has dropped by 31.5% since 2011.
- ▶ Beef cattle have replaced hay as the predominant commodity in the Highway 16 and North Cariboo region in the last decade (now hosts 35% of provincial total by head).
- ▶ Farm receipts in the Nechako increased by 24.5% in the last decade, well below the provincial increase of 63%.
- ▶ In the North Coast region, farm numbers decreased by 30% and farmland area decreased by 30%. Hay and horse farming sectors lost the greatest number of farms.
- ▶ Farm receipts in the North Coast region increased by 176% in the last decade, well above the provincial increase of 63%.
- ▶ In both regions the largest loss of farm numbers was for those with annual revenues under \$10,000. There was slight growth in farms with revenues over \$100,000 in the Nechako and notable growth in farms with revenues over \$50,000 in the North Coast.

## Regional Climate Change Impacts

The Highway 16 and North Cariboo region covers a large area of the province that has significantly different climatic zones, but all areas are experiencing the impacts of climate change. In general, drier summer conditions, more frequent and intense wildfires, and more intense rainfall in spring and fall have been observed.

The changes being observed in this region are consistent with the 2015 Pacific Climate Impacts Consortium (PCIC) 2050 projections. More recent climate models continue to show the same trends. Because the majority of agricultural production occurs in the North Cariboo, Bulkley-Nechako, and Fraser-Fort George regions, agricultural climate projections and data are focused here.

### PCIC Climate Projections: Bulkley-Nechako and Fraser-Fort George, 2050

#### TEMPERATURE

2.2°C to 4.3°C  
increase

in annual average temperatures

37 to 70  
more

frost free days annually

#### PRECIPITATION

13% increase  
in average spring precipitation  
(+5% to +21%)

16% increase  
in average fall precipitation  
(+9% to +26%)

Drier summer  
conditions

#### EXTREMES

Increase in frequency  
and magnitude  
of extreme rainfall events

Average of  
8 days  
over 30°C annually,  
up from 1 day

Projections provided by the [Pacific Climate Impacts Consortium](#) in 2015. 2050 averages are compared to the baseline historical period of 1961-1990.

# Nutrient Management

Photo: Shutterstock

Mitigation

Environment

Nutrient management is an essential step in maintaining soil function and optimizing crop yield and quality. Nutrient management practices involve applying the **right type of nutrient sources**, such as manure, fertilizer, or compost in the **right amount**, in the **right place** and at the **right time** for the specific crops being grown. Soil analysis and understanding crop nutrient requirements are important for informing nutrient application decisions.

A major reason for soil testing is to evaluate soil fertility, the ability of the soil to supply crops with nutrients. Effective nutrient management maximizes crop productivity and saves producers unnecessary costs of overapplication. Nutrient management is also crucial for environmental health, as undermanaged nutrient containment, storage, or application risks polluting surrounding water resources or producing greenhouse gas emissions. B.C.'s regulations surrounding nutrient management are outlined in the [Code of Practice for Agricultural Environmental Management](#).

## 1.1 Why is nutrient management a priority?

- ▶ **OPTIMAL CROP PRODUCTIVITY can be achieved through effective nutrient management.** Crop yields and crop quality depend on nutrient availability and uptake. Producers need soil test results and knowledge of crop nutrient requirements to make informed management decisions. Crops have different fertility needs and require commodity specific nutrient management to optimize productivity.
- ▶ **COST EFFICIENCY is achieved when producers don't bear the costs of unnecessary nutrient supply.** Input costs can be reduced as nutrient use efficiency is optimized.
- ▶ **NUTRIENT LOSS poses an environmental risk to water resources.** Excess nitrogen and phosphorus that are not used by crops can get into surrounding waterways or aquifers. Nutrients and pathogens from manure can pose health risks to humans and animals when they are consumed in drinking water. Excess nutrients (most commonly phosphorus) can cause algae blooms that damage aquatic ecosystems.
- ▶ **NITROGEN EMISSIONS pose climate and health risks.** Ammonia emissions can reduce air quality and negatively impact human health, and nitrous oxide is a potent greenhouse gas that contributes to climate change.

## 1.3 What’s Next: Looking Ahead

Optimal nutrient efficiency can help ensure crop quality and yield, cost efficiency, and environmental protection. On-farm management practices for nutrient management can be considered within three main strategies:

### On-Farm Management Practices

**Nutrient application and sourcing** focus on how, when, and which nutrients are applied to support optimal efficiency. Efficient use of nitrogen on farms can result in reduced greenhouse gas emissions. Practices include:

- ▶ Soil testing and analysis
- ▶ 4R nutrient management: right time, right place, right rate, right source
- ▶ Precision application (e.g., low trajectory manure spreading/injecting)
- ▶ Variable rate application

**Soil and crop management** is concerned with improving soil health and managing crops to enhance nutrient cycling. Practices can overlap with other priority areas, such as soil management, and include:

- ▶ Soil testing and analysis
- ▶ Crop rotation
- ▶ Cover cropping
- ▶ Reduced tillage
- ▶ Residue retention

**Reducing risks to the environment** from nutrient pollution occurs by reducing nutrient losses from the field to surrounding terrestrial and aquatic areas. Environmental protection is largely supported by effective nutrient, soil, and crop management strategies. Practices include:

- ▶ Buffer zones surrounding manure storage
- ▶ Effluent management
- ▶ Nutrient recovery and recycling
- ▶ Riparian protection and restoration
- ▶ Appropriate rates of application based on factors above

## Funding Programs: NUTRIENT MANAGEMENT

The Ministry of Agriculture and Food, with delivery support from the Investment Agriculture Foundation (IAF), offers the following funding programs that address nutrient management:

- ▶ [Environmental Farm Plan Program \(EFP\)](#)
- ▶ [EFP Beneficial Management Practices Program](#) - *nutrient and waste management projects*
- ▶ [B.C. Climate Agri-Solutions](#) (Agriculture and Agri-Food Canada) - *nitrogen management stream*

## Building on Recent Projects

### B.C. Living Lab:

- ▶ Cattle and Forage: Building on extended grazing and nutrient management on-farm trial sites to increase demonstration sites and extension opportunities

### Forage crops:

- ▶ Explore and trial nutrient optimization for forage stand productivity
- ▶ Explore and trial low-emission fertilizer application technologies
- ▶ Trial increased legumes in perennial forage stands
- ▶ Enhance soil testing and crop nutrient analysis opportunities for forage producers

# Water Storage and Development

Adaptation

Changing climatic, regulatory, and farm management conditions are impacting water storage and development needs in the Highway 16 and North Cariboo region. Water needs for crops and livestock are increasing as the region experiences lower than normal precipitation in the summer months. Sustainable water management is a priority for producers to maintain productivity and allow water sources to recharge for future use. Drought conditions have reached levels 3-5 (mid to maximum in [Provincial Drought Level](#)) across the region in three of the last five years during summer and/or fall periods. Drought levels in 2023 have been prolonged at level 5, marking the worst drought in the region’s history.

The 2021 agricultural census indicated that 18% of farms in the Cariboo are irrigated, compared to 10% in Bulkley-Nechako and Fraser-Fort George regions. Both regions may have increased water demand as the need for irrigation in the summer months increases. Concerns around agricultural water have also emerged with processing delays and communication challenges that have occurred with the rollout of the new groundwater licensing requirement in the [2016 Water Sustainability Act](#).

## 2.1 Why is water storage and development a priority?

- ▶ **INSUFFICIENT FORAGE and winter feed for livestock due to drought:** In dryland operations, reduced precipitation has led to significant declines in hay and forage yields (particularly in 2023), forcing some ranchers to buy feed they would normally grow themselves at demand-surge costs. Livestock producers across the province have been challenged with difficult necessary actions (e.g., reduction of herd size, feeding winter stock early,) and are relying on additional supports and programs.
- ▶ **WATER SUPPLY decreased by changing temperature and precipitation patterns:** Reduced summer precipitation and warmer temperatures are contributing to loss of ponds across rangeland areas of the Highway 16 and North Cariboo region. With decreasing water supplies, water quality is impacted, which can have effects on animal health. Variable snowpack and earlier peak stream flows are also contributing to water supply concerns in the Nechako watershed.
- ▶ **IRRIGATION EFFICIENCY increases water conservation through targeted application that ensures optimal amount and timing, reducing overapplication, evaporation, cost, and greenhouse gas emissions:** Increasing irrigation efficiency requires improved irrigation infrastructure that can have high up-front costs but result in cost savings over the long term.
- ▶ **ON-FARM WATER STORAGE that collects water during annual high precipitation periods can be an emergency water strategy:** At the farm level, challenges of implementation include cost and maintenance of storage infrastructure (tanks, dugouts) and volume of storage infrastructure relative to water demand.

## 2.2 What water storage and development work has been done?

## 2.3 What's Next: Looking Ahead

Sustainable agricultural water management is shaped by regulatory requirements, regional conditions, and farm level practices. Field-level or range-level water conservation and storage is a primary adaptation strategy for producers as they respond to reduced water supply associated with climate impacts.

### On-Farm Management Practices

**Field-level water conservation** is concerned with balancing increased water demands for crops and livestock with reduced water supply. Increasing water use efficiency can be achieved through targeted irrigation or watering systems that reduce overapplication and evaporation, and water quality protection measures that safeguard existing water supply. As the Highway 16 and North Cariboo region has primarily unirrigated farmland, all sectors face challenges to bridge the gap during periods of reduced precipitation. Practices to increase water conservation include:

- ▶ Water-efficient irrigation systems
- ▶ Irrigation scheduling
- ▶ Selection of drought-tolerant varieties
- ▶ Water quality protection measures (riparian buffers, nutrient management, contaminated runoff collection/storage/disposal, safe pesticide handling and application)
- ▶ Soil moisture meters and other technologies
- ▶ Rainwater collection and storage

**Climate-resilient livestock watering systems** can help ensure livestock have steady water supply through drought or freezing conditions. Natural water systems like ponds, streams, rivers, and even dugouts may be less reliable for direct watering through dry periods and warm temperatures and can have increased environmental risks from livestock use. Pumps and associated infrastructure can be useful alternatives. Many types of energy can be used to pump water and can be weighed against cost, producer preference, seasonality, number of livestock, etc. Specific infrastructure can include:

- ▶ Access ramps to direct sources
- ▶ Water gap fencing
- ▶ Moveable stock tank (e.g. on a trailer)
- ▶ Geothermal watering systems
- ▶ Solar/wind/streamflow/gravity/electricity/fuel powered pumps
- ▶ Pumped gravity flow reservoirs
- ▶ Nose pumps/frost free nose pumps (has integrated drain-back system)
- ▶ Pipelines (e.g. within intensive cell pasture system)

### Building on Recent Projects

#### Drought response:

- ▶ Provide knowledge transfer resources and local demonstration for water management best practices
- ▶ Support field-based water management demonstrations

**Water access and storage:**

- ▶ Improve informational resources and technical support for farm/ranch water storage development
- ▶ Complete localized/sub-regional agricultural water supply risk and opportunity assessments
  - Re-evaluate needs for agricultural dugout maintenance and upgrades
  - Pilot collaborative improvements of agricultural dams
  - Apply and trial new tools for livestock surface water risk assessment process
  - Support demonstration of resilient water developments in high-risk range units

## Crop Selection for Resilience

Photo: Emrys Miller

Adaptation

Environment

As the seasons become more variable, specific varieties of key crops that have historically been productive may underperform or become unreliable. Rising temperatures and increasing variability in temperature, frost, and precipitation patterns can reduce crop yields as well as create conditions for increased pest and disease pressures. Regionally adapted cultivars are bred within the region of intended production to ensure crop traits function well in the local area.

As the impacts of climate change accelerate, producers are seeking crop varieties that can still produce well in periods of increased water stress, disease, or pest pressures. Varieties that can endure a broader range of temperatures and precipitation levels are important. Increased climate variability and an increased number of growing degree days may also create opportunities for new crops and varieties in the region. Plant breeding and cultivar development is a slow process; upwards of 10 years may be needed to develop a new variety. This long timeline makes on-farm variety trials an important part of adaptation, so that farmers can better understand how existing varieties or varieties new to the region perform locally, and share farmer-to-farmer knowledge of region-specific data and observations.

### 3.1 Why is crop selection for resilience a priority?

- ▶ **CHANGING TEMPERATURE and extreme weather events can cause staple varieties to underperform.** Drought conditions and extreme events, such as the 2021 Western North America heat dome, have drastically reduced yield in staple varieties across commodities (notably forage). Varieties that are more heat resilient are beginning to be preferred by producers across the province.
- ▶ **CHANGING PRECIPITATION patterns cause seeding and harvest timing and frequency to change.** As precipitation load shifts into spring and fall, producers may need to shift seeding and harvest times and frequency. Some commodities may increase harvest frequency, others (e.g., hay) may be reduced.
- ▶ **PEST & DISEASE PRESSURE may increase due to changing climatic conditions:** as temperature and precipitation shifts across the province, some regions may become more susceptible to pests and diseases of concern.

## 3.2 What crop selection for resilience work has been done?

### 3.3 What's Next: Looking Ahead

The impacts of climate change on crops and associated pests and diseases are increasing, causing producers to implement strategies and practices to ensure crops are resilient. Practices for crop and variety selection for resilience fall into three main strategies.

#### On-Farm Management Practices

**Crop diversity and adaptation** focuses on selecting and developing a diverse range of varieties adapted to regional conditions. This strategy requires participation from producers, industry, and academia to develop and trial new varieties. Practices include:

- ▶ Regional adaptation of crop varieties with diverse selection
- ▶ Diversification of forage mixes
- ▶ Selection of climate resilient varieties

**Management for pest and disease risks** is achieved through a suite of practices that can help reduce losses associated with changing pest and disease pressures. Practices include:

- ▶ Crop rotation
- ▶ Integrated pest management
- ▶ Cover cropping
- ▶ Biosecurity to prevent introduction of new pests

**Monitoring and adaptive management** are critical to track the success of new variety trials. Practices include:

- ▶ On-farm research
- ▶ Continuous monitoring/scouting and data collection
- ▶ Real-time crop performance assessments
- ▶ Integration of local and Indigenous knowledge

#### Building on Recent Projects

- ▶ Coordinate local crop trials and farm practice research and demonstration with opportunities for farmer-to-farmer data sharing
- ▶ Improve regional weather station coverage and related decision support tools
- ▶ Establish and support regional weather network “hubs” to track detailed weather information to provide baseline information for regional crop selection and variety trials

Photo: Brenna Schildt

## Grazing Management Systems

**Adaptation**

**Mitigation**

Grazing management systems are concerned with planning when and where livestock are grazed. They aim to maintain or increase the economic profitability of grazing operations while maintaining the natural integrity of forage, soil, water, and environmental resources. There are several types of grazing systems for sustainable livestock management, depending on the size and type of grazing land and its suitability for natural or managed forage production and the type of livestock involved. Producers in the Highway 16 and North Cariboo are provincial leaders in adopting intensive grazing management practices, which are more common on tame or annual pasture. Silvopasture (a system that intentionally blends management of trees, forages, and livestock on the same land unit) is also used in the region.

Good grazing management should balance forage productivity and pasture health with livestock production. Indicators of a good grazing management system include consistent pasture cover with healthy and desirable forage plants, good soil water infiltration, good soil structure, healthy riparian areas, and maintenance of wildlife habitat.

Key infrastructure for all grazing management systems includes fencing, water developments, and mineral supplements. Rotational grazing can generate attractive revenues and can improve soil function and sequester carbon, but limited existing infrastructure and high cost of installation are among the challenges in the Highway 16 and North Cariboo region.

## 4.1 Why are grazing management systems a priority?

- ▶ **CROP PROTECTION** measures are becoming crucial to avoid severe impacts of extreme heat. **DEGRADED PASTURE** reduces forage productivity and soil capabilities that support adaptation to climate impacts: Overgrazing can lead to significant reductions in forage plant health and productivity, while degraded soil structure from a) compaction from equipment or livestock and b) intensive tillage practices reduce the soil's air porosity and organic matter content that are needed for good water infiltration, water retention, and root health.
- ▶ **SILVOPASTURE** is an agroforestry system that intentionally integrates the management of livestock, forage and trees: In B.C., use of silvopasture is less common than conventional forestry, range and pasture management but on-farm research and development are in-progress in several regions. Silvopasture can maintain or augment forage resources for both livestock and native ungulates and diversify revenue, while contributing to carbon sequestration, climate change adaptation strategies and environmental stewardship goals such as enhanced riparian area protection.
- ▶ **INTENSIVE GRAZING SYSTEMS** can optimize pasture health and livestock productivity: In contrast to continuous grazing where livestock graze a specific area throughout a year or grazing season, intensive grazing management systems divide pastures into intensively managed units where available area, livestock numbers, duration of grazing, and other tools are used to reach management goals. Intensive grazing management can be used to build and maintain pastures where desired forage plants provide nutritious above-ground growth and robust below-ground root systems that sequester carbon and improve water infiltration and soil structure.
- ▶ **FEEDING STRATEGIES** are essential to good grazing management, as they optimize livestock health and can support better pasture health and nutrient management: Ensuring optimal nutrition through selection of managed or native forage species safeguards livestock assets, while strategies such as bale grazing and in-field winter feeding can reduce impacts on soil and reduce manure buildup/risk of runoff in smaller wintering sites and corrals.
- ▶ **WILDLIFE CONFLICT** creates tension between agricultural production and biodiversity conservation: Striking a balance between agricultural production and wildlife conservation goals requires multi-faceted strategies and ongoing collaboration. In the Highway 16 and North Cariboo region, ungulates and large predators are particularly challenging for livestock and forage producers. As climate impacts shift wildlife habitats and patterns, impacts on agriculture may shift and require new management strategies.

### 4.3 What's Next: Looking Ahead

Producers are increasingly employing on-farm management practices that are included in sustainable grazing management systems. These practices can contribute to climate adaptation, reduction of net greenhouse gas emissions, and environmental management. In the Highway 16 and North Cariboo region, on-farm grazing management practices generally fall into two strategies:

## Funding Programs: GRAZING MANAGEMENT SYSTEMS

- ▶ [Environmental Farm Plan Program \(EFP\)](#)

- ▶ [Species At Risk Partnerships on Agricultural Land](#) (B.C. Cattlemen’s Association)
- ▶ [BC Climate Agri-Solutions –rotational grazing streams](#) (Agriculture and Agri-Food Canada)

### Provincial Toolbox: GRAZING MANAGEMENT SYSTEMS

[Grazing Management Guide](#)

[FaRM B.C. Advanced Grazing Systems Course](#)

## On-Farm Management Practices

**Intensive grazing strategies** can be designed to manage livestock in ways that protect or even improve soil properties that enhance forage and pasture production. On-farm management practices aim to reduce animal impact on soils by managing impact over time and space, which allows pastures to rest long enough for grass and other forage plants to regenerate. As livestock graze, plants have decreased leaf area to support photosynthesis and growth. Effective rest periods allow for plant growth/regrowth and can help maintain vigorous above ground and below growth development resulting in robust roots that maximize water and carbon sequestration and lush vegetation that provides optimal nutrition. Beneficial on-farm management practices include:

- ▶ Grazing management planning
- ▶ Rest periods for pastures (rotational grazing)
- ▶ Animal impact management (i.e. compaction, riparian areas)
- ▶ Stocking rate/density management
- ▶ Soil health management
- ▶ Bale grazing
- ▶ In-field winter feeding

**Resource and ecosystem conservation** are key outcomes of good grazing management that reflect grazing livestock production’s integration with natural systems in the Highway 16 and North Cariboo region. Practices such as riparian management, fencing, and habitat enhancement help livestock coexist with wildlife and natural systems. Practices include:

- ▶ In-field water developments
- ▶ Exclusion fencing
- ▶ Wildlife friendly fencing
- ▶ Riparian conservation
- ▶ Invasive species management
- ▶ Wildlife habitat enhancement
- ▶ Agricultural/wildland fuel management
- ▶ Stackyard fencing
- ▶ Conflict reduction planning
- ▶ Non-lethal deterrents and livestock protection practices

## Building on Recent Projects

- ▶ Improve informational resources and technical support for farm/ranch water storage development
- ▶ Develop a pilot project and resources for pasture health assessments and plans
- ▶ Conduct multi-year monitoring of the Bulkley-Nechako/Fraser-Fort George agricultural wildland interface fuel management pilot site

# 5 Soil Management

Photo: Shutterstock

Adaptation

Mitigation

As climate variability and extreme events increase, appropriate soil management practices are critical for agricultural resilience. Soil properties that generally improve the capability of soils to sustain crop production include porosity for air circulation and water infiltration and retention. Site-adequate organic matter is also essential to support soil biological and chemical processes that convert nutrients into plant available forms. Maintaining soil cover and reducing disturbance can often help to maintain and enhance soil properties on-farm. It can also support soil processes that improve crop productivity and enhance overall farm resilience.

Soil health outcomes are influenced by many factors. Some issues and management strategies are sector specific, but several are common challenges across commodities in the Highway 16 and North Cariboo region. These include limited access to soil testing, diverse soil conditions that make the applicability of recommended soil management practices unclear, and lack of soil classification data.

## 5.1 Why is soil health management a priority?

- ▶ **SOIL DEGRADATION reduces resilience to climate change impacts:** Degraded soil structure from compaction by equipment or livestock, or intensive tillage practices, reduce the soil's air porosity, which is needed for good water infiltration, water retention, microbial activity and root growth.
- ▶ **NUTRIENT CYCLING processes that support natural soil fertility can be optimized in well-managed soils:** The soil organisms that cycle nutrients and make them available for plants rely on organic matter, suitable pH and adequate physical soil properties. Supportive practices include adequate organic matter amendments, cover cropping, maintaining soil cover, and reducing soil degradation. In the Highway 16 and North Cariboo region, the success of cover cropping is site-specific; for example, short growing seasons and limited irrigation infrastructure increase the challenges of cover crop adoption and establishment.
- ▶ **CARBON SEQUESTRATION in some soils can be enhanced using certain soil management practices:** Soils that have vegetative cover and carbon-based inputs like compost or manure have generally higher organic matter content and can play a role in mitigating climate change by reducing carbon dioxide in the atmosphere. Practices such as intensive tillage, or those that result in bare soil, can reduce soil carbon sequestration.

## 5.3 What's Next: Looking Ahead

Producers are increasingly employing on-farm management practices that aim to improve soil properties and processes that support productivity and resilience. These practices can contribute to climate change adaptation, reduction of net greenhouse gas emissions, and environmental management. In the Highway 16 and North Cariboo, soil health management practices generally fall into two strategies:

### On-Farm Management Practices

**Pasture rejuvenation strategies** support soil and forage productivity by stimulating release of soil nutrients and creating opportunities for robust root systems of preferential forages to develop. Pasture rejuvenation may also improve water infiltration, facilitate carbon sequestration, and extend the land's productive life. On-farm practices include:

- ▶ Periodic pasture reseeding/overseeding
- ▶ Mechanical aeration
- ▶ Targeted fertilization

**Conservation and management of soil organic matter** is critical to climate adaptation and mitigation. On-farm management practices such as retention of vegetation and reduced tillage can conserve soil structure and organic matter, but success of implementation is site-specific; several areas of the region have low natural soil organic matter. Practices include:

- ▶ Cover cropping (and plowing in cover crops)
- ▶ Organic matter amendments (e.g., compost)
- ▶ Inter-seeding
- ▶ No-till seeding
- ▶ Reduced tillage
- ▶ Integration of woody perennials (e.g., shelterbelts)
- ▶ Conservation tillage (e.g., tillage retaining crop residues)
- ▶ Nutrient management

### Building on Recent Projects

#### B.C. Living Laboratories Projects:

- ▶ Cattle and Forage: Building on extended grazing and cover cropping on-farm trial sites to increase demonstration sites and extension opportunities

#### Recommendations from the Minister's Advisory Group on Regenerative Agriculture and Agritech:

- ▶ Identify and share best soil management practices using a producer-centric approach for implementation and knowledge sharing
- ▶ Identify practical indicators of properties that support soil relevant functions, measure, and communicate baseline values at farm, regional, and provincial levels; determine realistic improvement goals; measure the impacts of practices

### Funding Programs: SOIL MANAGEMENT

The Ministry of Agriculture and Food, with delivery support from the Investment Agriculture Foundation (IAF), offers the following funding programs that address soil management:
